THE PERMANENT PRESERVATION OF ANATOMIC, EMBRYOLOGIC, PATHOLOGIC AND BACTERIOLOGIC SPECIMENS

W M L COPLIN, M.D
Professor of Pathology Jefferson Medical College
PHILADELPHIA.

[From the Laboratories of the Jefferson Medical College Hospital]

In teaching by modern laboratory methods, nothing is more important than the artistic and accurate preservation of material in such a manner as to retain permanently the natural colors and secure mounts that conveniently can be labelled, handled and exhibited The old methods, yielding uncolored, bulky masses, possessing, save in form, little resemblance to the original, gave most unsatisfactory results, and hence museums more than five or ten years of age no longer meet the requirements of to-day The specimens I exhibited at the Atlantic City Session of the Association received such flattering notice, and so many have written for the details of the method, that it seems desirable to publish in full the various steps necessary to attain the results shown Except in minor details (which are essential), the method makes no claim to originality, it is the assembling of what seemed the best in several methods, published and unpublished, and still is replete with possibilities that have not been worked out Undoubtedly the method could be applied to the preservation of botanic specimens, but having no facilities for experiment in this direction I have not attempted to adapt it to that purpose

The method is based on the well-known Kaiserling process, and the permanent preservation in gelatin is but a modification of the old glycerin-jelly medium, long a standard agent with microscopists Much of the detail requiring experiment has been worked out by Dr John Funke, to whose patience and care the beautiful results obtained are largely due Petri dishes, mounted on glass plates, were first brought to my attention by Dr S W Sappington who used ground glass, which obscured one side of the specimen, but nevertheless yielded very beautiful results

Dr H E Radasch associate in embryology in the Jefferson Medical College, has worked out the technic of attaching letters to the specimen so that the label may be made descriptive, like the legends in our text-books My secretary experimented with various typewriter ribbons and eventually found that the stock article called "The Record Ribbon" met all requirements

THE FI the od UID

The a changed The method o treatment of anato most economical but probab id (2) the developer, and (3) the final preservative, and for these purposes I have utilized the generally accepted fluids of the Kaiserling method The fixation fluid is composed of

Formalin (any 40 per cent aqueous solution of formaldehyd gas serves equally well)	250 c c.
Potassium nitrate	10 gms
Potassium acetate	30 gms
Water	1,000 c c

he
inche

The salts are dissolved in the water and the formali then added It is desirable, but not strictly neces that the salts be chemically pure, a good comr ortant, article gives satisfactory results, but many specim ny spr n is the salts contain iron, and even traces of this m what sary, tend disaster For this reason no metal is pe d th ercial come in contact with the solution or the spec h a mens of ing any stage of their preparation, the only er t etal por- this rule has been the occasional use of lea all rmitted to ing down such organs as lungs and also imens dur- other tissues that tend to float, but even f exception to pieces of tile, brick or crockery are better ld for weight- is made in fifteen-gallon jars, with lips lipomata and form commercially used for the pres or this purpose kraut The mixture and lids of the xation of sauer-

THE DEVELOPER AND THE PR VATIVE

The developing fluid is alcohol iters (includ- ign Kaiserling) recommend two st an 80 per cent and a 95 per cent, but we use he ordinary commercial article So far as we ca ve, methyl alcohol possesses no advantages

The final preservative, in its liquid the fol- lowing formula

Acetate of potassium
Glycerin
Water

is

The acetate and glycerin are thoroug the water added The order is probably tance in the preparation of either this d fluid, but in the latter one wishes to delay th formalin as long as possible, as it is quite m to stand over and stir the mixture after the fo is added One word with regard to the water distilled water is best but some tap waters m be used water from any mechanical filter using alum can not be trusted Filtration of the fixation fluid is unnecessary the preservative should be filtered through a thick pad of cotton placed at the bottom of a large funnel or percolator As soon as the final fluid is prepared a lump of thymol (about 15 to 20 gms) large enough to be seen and easily handled is placed in the container and each vessel of the final preservative should contain a piece of thymol sufficiently large to be picked out or left in the vessel when the fluid is poured out or used When specimens are permanently preserved in this solution, a lump of thymol should be kept in the jar to prevent the growth of fungi

THE GELATIN MEDIUM

The solid medium in which the preparations are finally preserved is a 10 per cent solution of gelatin in the acetate of potassium glycerin and water mixture This is prepared by soaking the requisite amount of gelatin in the mixture for 12 to 24 hours, the container is then placed on a water bath or in flowing hot water until the gelatin melts, this takes but a short time The mixture is rendered decidedly acid to litmus by the addition of acetic acid, about 1 c c to the liter, and clarified by the use of egg albumin exactly as in preparing gelatin media Acetic acid favors complete coagulation of the albumin, tends to make the gelatin clearer and, as originally suggested by Williams acidity seems to assure better color preservation The broken shells and whites of four eggs should be used for each liter of the mixture After filtration the prepared medium is bottled and placed on ice until solid, and then a large crystal of thymol is thrown on top of the solidified gelatin and the container stop- red Prepared in this way, the medium keeps until led When wanted, the crystal of thymol is removed forceps and the gelatin liquefied at a low tempera The thymol should be taken out before warming itin otherwise it evinces a tendency to fragment, is dissolved in such quantity that, when the fluid a precipitate forms rendering the medium l slightly opaque It is well known by bachat gelatins differ, and we have found at that can not be cleared satisfactorily The hat has given us the best results is that cially as "W H No 1,866" Some gelaitain a masked coloring which causes the ative to appear decidedly red it should olor and perfectly transparent Care is ude iron and hence the gelatin should beakers or porcelain vessels, new agatecracks or shales may be employed, but it worthy that time and patience are saved by I have not tried copper, but judge the exic acid would render its use risky

THE SPECIMEN

of the highest importance that the material to be ved shall be received in a proper condition Fresh- a prerequisite, when the blood has begun to yield oloring matter and imbibition has tinged the specin, only a motley result can follow Our results with pecimens that have been frozen or iced for any time, even if the colors at the beginning of the process seemed good, have not been satisfactory Nothing shows this better than a pair of kidneys received fresh from an autopsy, one carried through immediately, and the other iced or kept in the refrigerator until the next day, when its preparation is begun, when obtained the organs may have appeared identical, after preparation the resemblance is superficial The influence of blood imbibition (I use this term for combined hemolysis and hemoglobin diffusion as the hackneyed expression of the autopsy room) is such that a specimen left in a pan or on a plate containing a little blood-stained fluid will carry the markings of the latter to the end If fixation at once is not practicable, rinse off the blood stains and wrap the specimen in sufficient gauze, or a number of towels, to absorb any fluid that may escape, the fact that fluid escapes is proof that something is being lost, and it is attention to just such details that assures success

THE ORIENTATION

This is a most important step The specimen is arranged, posed or oriented just as it is to appear when mounted, during fixation the stiffening action of the formalin gives a permanent shape even to such thin specimens as the intestine, and readjustment of such organs as the heart, lung, kidney or bladder becomes impossible In this orientation every thread tied across the specimen will leave its mark, and each hole made will show, iron (tacks) can not be used, and even the slender entomologic pins leave small black holes, white thread (linen) is best, for pinning, wooden or quill toothpicks may be used A number of cork blocks, 25 cm square and 3 5 cm thick, are especially useful for attaching and holding organs in position, intestine and other membranous specimens may be wound around such a block The disadvantage of cork is the weight necessary to sink it, but even with this drawback it is better than glass If both sides are to show, it is best to sew the specimen in a glass frame arranged for permanent mounting If spread on cork or glass, four layers of thick, tough filter paper free from lint should be interposed between the specimen and the cork or glass Cotton serves as well, but fixes tightly to albuminized surfaces, towels and cheesecloth are prone to mark the specimen with a screen effect The cork, with the attached specimen turned downward, is thrown in the fixation fluid, and a brick placed on the top submerges the specimen and part of the cork Care should be taken that the center of the specimen does not fall away from the cork, this can be prevented by obliquely placed toothpicks Although highly recommended, we have not resorted to injection through the blood vessels, but for very large masses or the fixation of organs like the brain and liver it might be highly advantageous Cysts, hydronephrotic kidneys, unopened intestine, stomach and other specimens containing cavities may be distended with the fixation fluid and sectioned later

The formalin solution accomplishes more than one purpose It fixes the specimen, I presume fixation is a coagulative process, at least in part, but it is more, the exact nature of the chemical change I shall not discuss at this time The specimen stiffens, blanches, and becomes more or less friable and inelastic, the color changes appear to have ruined the mount The fluid not only fixes, but also sterilizes the specimen, and, although surface color and contour may be preserved by surface fixation, penetration is necessary for satisfactory permanent preservation For this reason a change to a second container of the fixation fluid is advised The cork block or other retentive device is no longer needed, and in the second jar the specimens are packed lightly with towels or cotton at the bottom and interposed between As soon as the first formalin solution becomes soiled it is thrown out the second is moved back to become the first, the emptied container is washed and filled with fresh solution and replaces the second jar, now moved back to become the first The solutions may be used repeatedly, provided specimens containing bile are excluded Sometimes bile-stained specimens turn very green, all other colors being thereby obscured, such organs, usually livers, greatly discolor all the fluids into which they are placed In preserving livers it is well to wash the bile from the gall bladder and rinse the surface of the o thoroughly I would advise, under all circumsta pecimens of liver be carried through sepa which one can foretell ho me-times no green tint develops, and beautiful color differentiations are obtained, we have no finer specimens than some of red atrophy put up over a year ago

The most puzzling and unanswerable question, and at the same time an exceedingly important one, is how long must the formalin act? This depends entirely on the size and consistency of the specimen A piece of stomach, intestine, diaphragm or other membrane will have fixed fully after three hours in each of the two formalin solutions Half of a kidney should be left at least twelve hours in each solution, and a brain twenty-four hours in each solution Prolonged immersion in the fixative solution may render development of the color impossible, but on the other hand under-fixation is sure to leave the blood coloring matter soluble, so that it washes out or diffuses in the later handling Large specimens, such as brains, livers, and even kidneys, if not sectioned when placed in the first solution should be freely incised, or, better, cut into slabs 4 to 8 cm in thickness before entering the second fixing solution

THE WASHING OUT

The next step is getting rid of the excess of fixation fluid This is accomplished by washing in running water for fifteen to twenty minutes, after which the specimen is transferred to the first alcohol In my estimation the success of the process depends on the care and judgment exercised in the development of colors in the alcohol The process should always begin in the morning, as I know of no safe criterion by which it is possible to foretell the length of time that will be necessary, and, as daylight is essential to watching the evolution of color, late afternoon and evening hours must be avoided The excess of water is mopped off and the specimen completely submerged in commercial alcohol (94 per cent), the color begins to appear in a few minutes, and as soon as it is fairly under way the tissue should be transferred to the second alcohol, and when restoration of color is complete the organ is quickly drained and submerged in the final preservative When the restoration of color is complete fading begins, progresses rapidly, and once the color is lost in alcohol, I know of no way by which its return can be secured, hence the process must be watched carefully The stay in alcohols is also influenced by the future treatment to which the specimen is to be subjected If it be a membrane, like a piece of intestine, even twenty minutes to a half hour for the two alcohols may be excessive on the other hand, if it be a slab of an organ, the surface of which can be shaved down to the point where the alcohol has penetrated just to the proper degree, less care is necessary and over-development less likely to prove disastrous As soon as the color is restored further action of the alcohol must be arrested by immersing the specimen in the first container of the potassium acetate, glycerin and water mixture where it should be fully submerged and allowed to remain for the same length of time that it was in the alcohols, after which it is transferred to the second jar of the same fluid in which the preservation may be permanent, or after one or two weeks preferably sooner, the mount is completed in formalin-glycerin-gelatin The first and second alcohols and the final preserving fluid are changed from time to time in the same way as already directed for changing the fixation fluid sooner or later the first alcohol gives off strongly the odor of formalin and the first preservative yields the odor of alcohol when both should be changed The method of changing suggested is the most economical but probably is not so good as the complete renewal of all solutions, however, we have found the way advised efficient

Specimens prepared as suggested preserve their color fairly well, to a large degree the permanency depends on the freshness of the material Most observers lay great stress on the necessity of excluding light, probably darkness is better, but the chief difficulty lies in the macerating and solvent action of any solution, and to avoid these dangers a permanent solid medium is to be recommended, and for this purpose formalin-glycerin-gelatin is almost ideal

FORMALIN-GLYCERIN-GELATIN MOUNTS IN PETRI DISHES

The pieces of plate glass and Petri dishes used in preparing the mounts vary in size The largest Petri dish that we have used is 20 cm in diameter and requires a plate glass 9 by 11 inches The following table gives the sizes of Petri dishes and glass plates necessary for all ordinary purposes, the conversion of the metric measurements to inches is approximate

Petri Dishes	Plate Glass.
20 cm	22 5x27 5 cm, 9x11 inches
15 cm	20 0x22 5 cm 8x 9 inches
12 cm	20 0x22 5 cm 8x 9 inches
10 cm	12 5x17 5 cm, 5x 7 inches
8 cm	12 5x17 5 cm 5x 7 inches
6 cm	10 0x12 5 cm 4x 5 inches
5 cm	7 5x10 0 cm, 8x 4 inches

The thickness of the plate glass is important, as thin pieces are often bent in handling, and any spring tends to loosen the attached dish No matter what the surface dimensions, I am strongly convinced that the glass should not be less than one-fourth inch and, better, three-eighths inch in thickness, a greater thickness might be desirable, but would add materially to the bulk and weight The Petri dishes should be free from bubbles or rings, and when placed with the edge on plate glass should not rock, thus showing that the edge is true The specimen to be mounted is placed in the dish, and this is filled with final preservative for the purpose of ascertaining the quantity of gelatin that will be needed to complete the mount We will say that this is found to be 100 c c Take 120 c c of the prepared gelatin, liquefied, and pour about one-half into the Petri dish, which must be thoroughly cleansed, place the specimen in this, carefully excluding air bubbles, and press it close to the bottom of the dish, using a light tile or glass weight if necessary Even when every care is taken gelatin poured from one vessel to another tends to froth or form small bubbles which, after congelation, are difficult to remove, wherever such a bubble forms, it should be sucked up in a medicine dropper while the medium is still fluid When properly oriented, dish and contained specimen are set aside in order to solidify the gelatin, using an iced chamber or the refrigerator, if the temperature of the room is too high The mount may be left in this condition for several hours if desired, or mounting may be completed as soon as the gelatin is solid Prolonged or too great cooling may cause corrugation of the surface retraction from the sides of the dish, and permits less perfect fusion of the gelatin added later, and for these reasons is not recommended

To complete the mount, pour on the solidified medium sufficient formalin to render the contained gelatin 0 75 per cent. formalin when the mount is completed For example If 100 c c of gelatin is necessary, 0 75 c c. of formalin should be poured on the solidified layer Fill the dish with the remainder of the gelatin and place it on a piece of glass resting on the table in such a way that both can be picked up readily while in this position put in place the glass plate that is to cover the P dish As soon as the plate is in the desired position, grasp the mount between the two glass plates, turn it over quickly, and run a ring of gelatin around the junction between the plate and the dish This is necessary because as the gelatin solidifies it contracts, and in the absence of an excess at the line of contact between plate and Petri dish such contraction may permit the entrance of air Set the dish aside for a few hours (over night or longer), until the gelatin is completely set Run a knife around the Petri dish, holding it parallel with the side of the dish, thus cutting the gelatin loose from the side, the excess may readily be stripped off Wash the plate quickly in cold water, dry rapidly, and with a dropper run a thin band of gelatin containing 1 per cent formalin around the line of contact between the Petri dish and the glass plate This will quickly set and in a day or so may be painted over with xylol balsam applied either with a brush or dropper, the first layer of balsam should be thin As soon as the balsam ceases to be sticky to the finger a second coat is applied, and this should be repeated until a sufficiently thick rim has been made I have no doubt that a turn-table would be convenient for the application of the gelatin and balsam rings but we have not found such an appliance necessary It has been suggested that the initial gelatin ring might be chromicised by the addition of bichromate of potassium, or by painting it over with a bichromate solution after it has solidified A number of cements, including Bell's cement, asphaltum and gold-size, have been tried, but seem to possess no special advantages

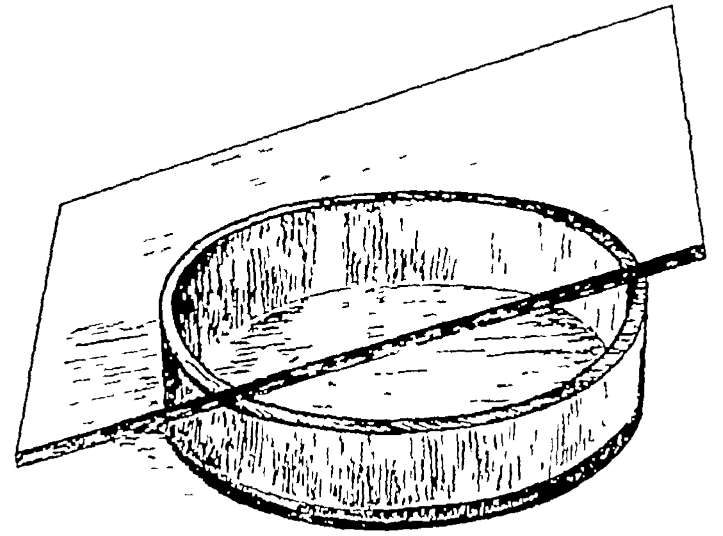

Fig 1 —Method of applying the cover by tilting it over the dish The specimen and contained gelatin are not shown in the illustration

The most difficult part of the procedure is adjusting the glass plate on top of the Petri dish in such a way as to prevent the entrance of air at the time the mount is made In the accompanying sketches (Figs 1 and 2) an attempt is made to show how the plate cover is applied, one method is by tilting it in position, and the other by sliding it over the dish By the latter method a slight band of gelatin is kept ahead of the advancing plate, thereby preventing the entrance of air Dr Funke, who has been most successful in the preparation of these specimens, likes this method for the larger Petri dishes During the experimental work necessary to perfect the process I was more successful with the other method As neither is satisfactory under all conditions, some worker should be able to devise a means that is better than either We have seriously considered submerging the dish either in gelatin or in water, but the methods detailed have been adequate In the beginning there will be some difficulty in excluding air, but with a little experience one is able to secure satisfactory results I do not know that a little air does any harm, although our experience has been that an air bubble invariably goes directly to the place where one does not desire it Dr Funke suggests that specimens having irregular and corrugated surfaces that afford numerous depressions in which air bubbles may lodge should be coated with gelatin before any attempt is made to mount them Intestine frequently requires such treatment He advises me also that lungs and other specimens containing spaces occupied by air be placed in a vacuum or chamber in which the air is rarefied in order that the gas in the interstices may more rapidly be displaced by the gelatin We have not tried this method, but suggest it as a possible solution of the difficulty frequently encountered in the preparation of lungs The gelatin infiltration would be facilitated by immersing such specimens over night or longer in the medium kept liquid in the incubator

Often a thin specimen would require so much of the medium to fill the dish that the resulting weight would make a cumbersome and unwieldy mount This difficulty may be overcome by attaching the specimen to the dish by means of gelatin, and leaving the remaining space empty This is best accomplished by flooding the surface of the glass plate with formalin-glycerin-gelatin, the specimen, for example a piece of intestine, is removed from the preserving liquid, lightly blotted with a towel and pressed into the gelatin, which quickly sets The surface of the specimen to be viewed is left uncovered As soon as the gelatin has set firmly, a slightly-warmed Petri dish is inverted over the specimen and pressed into the gelatin, the excess of gelatin outside the dish is removed with a knife or spatula, a narrow rim of gelatin painted around the junction between the Petri dish and the plate, and the seal completed by xylol balsam or other cement, as already directed Sometimes such mounts loosen from the glass, but this difficulty has given us no trouble except in thick, weighty specimens, such as slabs of liver and bulky pieces of lungs It could have been avoided by making thinner slices We strongly advise this method for exhibiting the granular surface of a specimen where the unevenness would be obliterated by submersion in gelatin It is recommended for exhibiting the granular surface of an incised lung in the red stage of croupous pneumonia, and for hemorrhagic infarcts So far as we can see, the color preservation is fully as good as in submerged preparations The method should be especially useful for

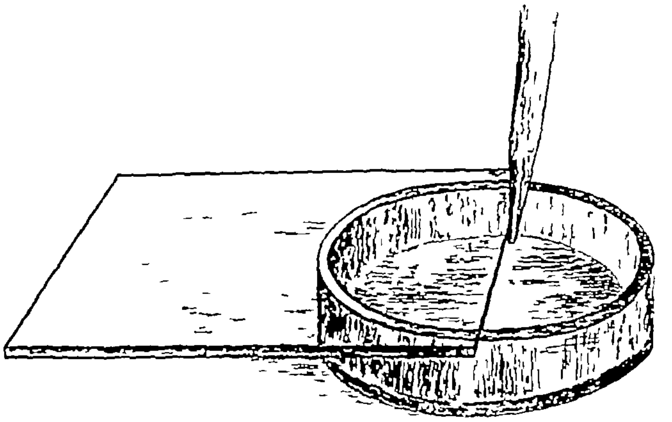

Fig 2 —Sliding the glass plate into position A Medicine dropper by means of which a roll of fluid gelatin is kept in front of the advancing plate This method is especially adapted to large mounts

the mounting of large brain sections, or slabs, for teaching purposes If the Petri dish be shallow, so as to throw the specimen near the surface, an excellent view can be obtained Mounting on the surface of gelatin is adapted to the exhibition of animal parasites that have been preserved by any of the formalin methods commonly used

The principle can be applied to gelatin plates containing colonies If the plates are in Petri dishes it is only necessary to invert the dish on the glass plate, ring it with gelatin and complete the seal as already directed If the old method of plating on glass, as originally advised by Koch, be used, the inverted Petri dish is warmed, a few drops of formalin placed on the gelatin, and the dish gently forced into position, the surrounding excess of gelatin is removed, and the sealing completed

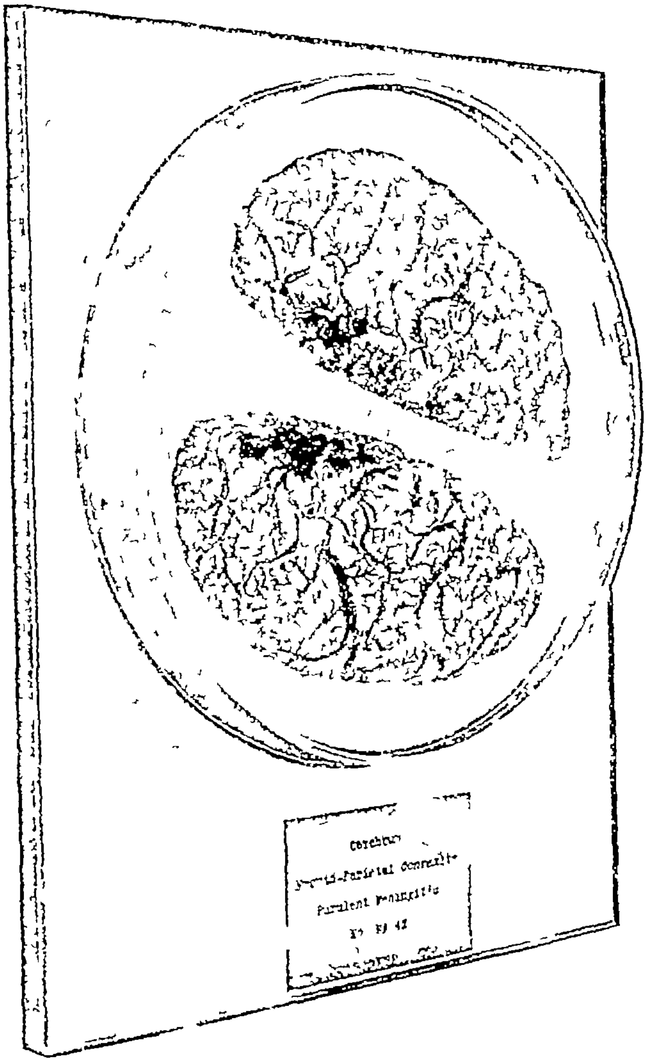

Fig 3—Completed mount in formalin glycerin gelatin All parts of the mount are well shown except the ring of cement joining the Petri dish to the glass plate unfortunately the photograph has not brought out the transparent ring of balsam The actual size of the glass plate is 22 5 cm by 27 5 cm (9 by 11 inches) The specimen is a part of the brain surface showing slight exudate and areas of hemorrhage case of purulent meningitis

LABELLING

The card used for labelling is the ordinary plain index card of medium thickness, on both sides the necessary legend is typewritten, using a "Record Ribbon" the card is now trimmed so that at each edge it will be one-eighth inch narrower than the slide or other glass intended to cover it The card is thrown into pure formalin and turned from side to side to prevent warping While the card is soaking in the formalin (for which only a minute or so is necessary) a slide is cleaned by any of the approved methods As a cover for the label we use a 2-inch by 3-inch slide, selecting, of course, the thinnest and most perfect with smooth edges A 10 per cent solution of gelatin, while still warm, is poured on the slide, the label is removed from the formalin, blotted between folds of filter paper, and quickly pressed down into the gelatin, a piece of filter paper is laid over it, and the label forced firmly against the slide, to which it adheres As soon as the gelatin is set, which takes but a minute or so, the slide and its attached label are placed in the formalin solution to complete the fixation of the gelatin The area on the glass plate selected for the label is now cleansed and some gelatin poured on the surface The label and attached slide are removed from the formalin, blotted with filter paper and pressed down on the gelatin, the label, of course, going next to the glass plate Weights are placed on the surface of the slide to force it into position, and the gelatin is allowed to pile up around the edges After the gelatin is set firmly, a knife is run around the edge and the excess removed, as already described for the dish A thin layer of gelatin is painted around the edges of the slide, and this, when dry, covered by xylol balsam in the same way as already directed for fastening Petri dishes in position Where there is room for the label, it could be placed beside the specimen within the Petri dish, however in that position it is more difficult to read and less readily seen when the mount is placed in a case Dr Radasch desired to label different parts of mounted embryos in such a manner that students handling the preparations could identify certain structures I had wished for the same thing and looked in vain for indestructible letters that could be used Dr Thomas C Stellwagen, Jr, kindly made for me some amalgam letters that we attached to specimens, but the process was laborious and time-consuming Dr Radasch found a typewritten letter could be used, the paper containing the letter is trimmed to the desired size, immersed in formalin, removed, rapidly blotted, grasped in forceps and inserted in place while the imbedding gelatin is still fluid He has many exquisite preparations lettered in this way, the labels constituting legends similar to those in our textbooks

When completed, such specimens make artistic permanent mounts (Fig 3) The gelatin lacks the macerating effect of fluids, and, so far as we can observe, preparations two years old are as fresh to-day as when first mounted The mounts can be handled with wet hands they may be washed with soap and water, and, as all parts are under glass, they are indestructible except by breaking The fact that they are glass and appear much more fragile than they really are lead students to manifest care in handling them Many of the preparations have been handled by hundreds of students and none has been broken That they are not exceedingly fragile is indicated by our experience at Atlantic City Nealy one hundred of these mounts were sent to the Session and when the boxes were opened not one was found broken, two were dropped from the table, and one of these cracked, but was not withdrawn from the exhibit few visitors noticed the break In returning from Atlantic City three were broken, but the packing was not well done

SPECIAL RECTANGULAR JAR

While the gelatin method is especially adapted to mounts of membranes, tissues in thin slabs and relatively light preparations, there still remain a number of specimens that conveniently can not be prepared in this way Over a year ago[1] I described a jar and adapted a clamp that, with some improvements, we are using today This device (Fig 1) consists of (1) a glass container (2) a special metal clamp contrivance for securing a water-tight seal, and (3) includes two special labelling devices The jar is 20 cm high, 10 cm wide and 4 cm thick When properly constructed the wall is practically the same thickness (0 4 cm) at all points Imported jars are recommended, as attempts to secure a jar of uniform thickness in this country have been unsuccessful American manufacturers seem unable to make a jar that is not thinner at the corners, and therefore unadapted to our purposes The clamp consists of two plates and two vertical rods which pass through the top and bottom plates, drawing these firmly to the jar by means of threads and nuts on the upper ends of the rods The rods are split above the top plate for the reception of a label, which consists of an ordinary index card, on both sides of which the legend is *written* The bottom of the jar is solid and rests on a rubber cushion, the top is closed by a similar rubber cushion that fits accurately into a recess that, in the figure, conceals it These cushions are made of extra heavy, steam packing rubber that in cylinder heads of engines lasts for months With the imported jar having thick sides the seal is perfect and in our mounts has remained so for over one year If the jar be opened or the fluid changed often it may be necessary to renew these rubbers, which are comparatively inexpensive Thin membranes, intestines and other specimens possessing too little rigidity to retain a permanent shape and position are attached to a frame made of glass rod

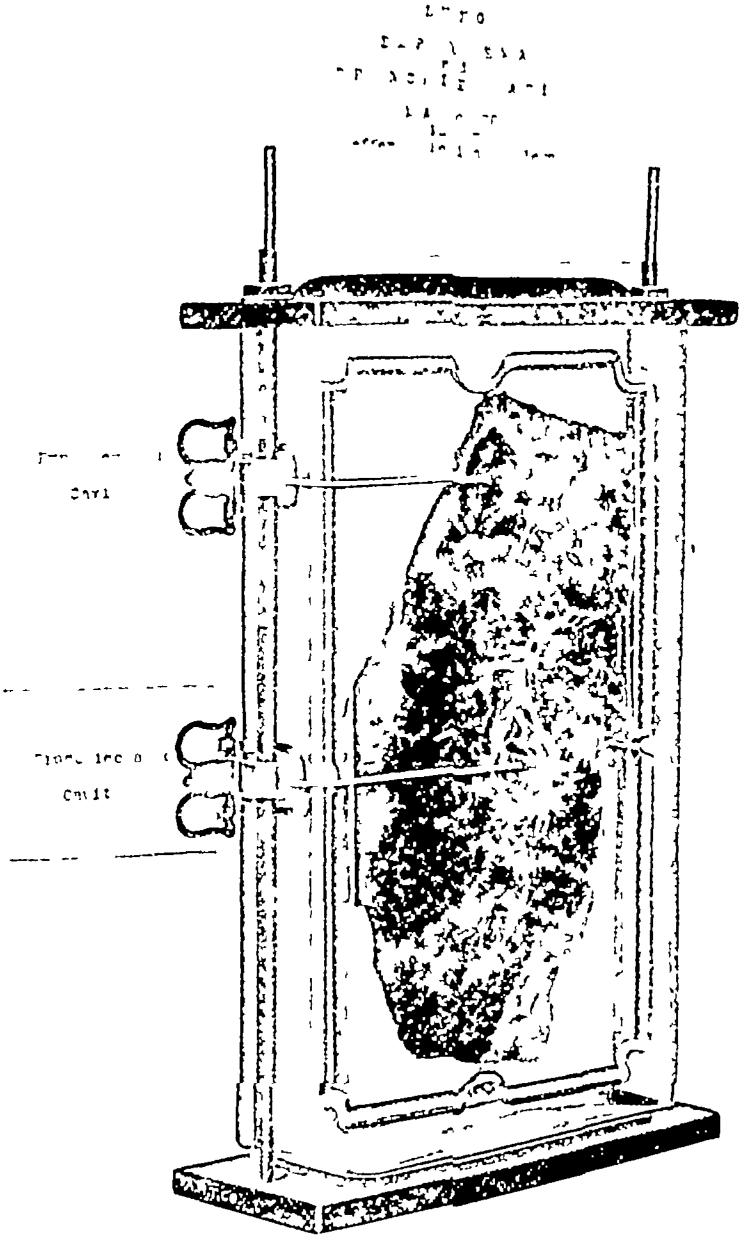

Fig 4—Improved rectangular jar, clamp and labelling device described in the text. The specimen photographed is a thin slab of lung showing emphysema and bronchiectasis Contrary to the rule in such cases it is decidedly red the high color being due to co-existing congestive condition resulting from associated cardiac lesions This relatively bright red color has prevented accurate reproduction of the specimen The labelling devices are well shown In retouching the photograph the glass frame by which the specimen is suspended has been made unduly conspicuous, as there was no way by which we could determine how much detail would be lost in the reproduction as a matter of fact, the frame is scarcely discernible when in position and covered by fluid Reproduction five twelfths natural size

A device that seems to me would be extremely advantageous in teaching is a labelled pointer than can be adjusted vertically on the rods at the side of the jar, and is used to indicate any particular point on the specimen to which it is desired to draw special attention These pointers can be placed at any height, are easily shifted from place to place, readily transferable from jar to jar, and any number desired may be used on one specimen

When properly sealed the jar may rest in any position, and of all devices for the preservation of specimens in a liquid medium it is most economical in space and fluid It requires but 5 cm (2 inches) shelf width and 13 cm (5¼ inches) base, so that seven jars without lateral cards can be placed on a shelf 6 cm (2½ inches) wide and 88 cm (36½ inches) in length The amount of lateral space occupied by labels supported on pointers depends, of course, on the size of the cards used for such labels Even under unusual conditions such cards should not be over 5 cm (2 inches) in length, and as but 4 cm of this projects beyond the base of the jar 17 cm (6¾ inches) will afford ample lateral space on the shelf, the depth of which remains the same as when side labels are not used I have considered cases for these jars, and also for the gelatin mounted preparations, built on the principle used in the construction of sectional bookcases, and, should directors of museums find such jars acceptable stacks could be arranged similar to those used in libraries where ready access to volumes is desirable[2]

Education of a Doctor—The layman who reads the proceedings of a medical congress in these days will be impressed with the fact that the practice of medicine has become a very serious business, and the preparation for it an arduous undertaking The old fashioned doctor, who got what training he had from a voluntary attendance on two terms of didactic lectures, aided by the reading of a few text-books and a possible association with an older practitioner, started out on his professional career with everything to learn, and his success or failure depended mainly on the personal qualities which he brought to his work Personal character and fitness are no less essential now than before, but it is simply impossible at the present time for a man to start out on the practice of medicine with the slender equipment allowable a generation ago It is not merely that the colleges require more preparation for a degree, they require more because the practice of medicine has developed into a science to be acquired laboriously —*Philadelphia Ledger*

WHAT CREDIT, IF ANY, SHALL BE GIVEN THE HOLDERS OF BACCALAUREATE DEGREES FOR ADMISSION TO ADVANCED STANDING IN MEDICAL SCHOOLS? *

HENRY L. TAYLOR, Ph.D.
University of the State of New York
ALBANY, N. Y.

PRINCIPAL CAUSES FOR THE DISCUSSION

When beginning preparation on this paper I was surprised to find how closely the closing paragraph of my remarks before this Association last year applied to the theme of this year's discussion. The substance of this paragraph may properly begin the discussion of my topic:

The allowance to be made graduates of colleges of liberal arts and science must receive careful attention. The independent colleges and medical schools suffer by the drifting of their students to the universities that can afford both lines of work and a combined course, saving one or two years of time. The presidents of independent colleges plead for subjects that they regard as essential to liberal culture—for example, psychology—while the deans of the independent medical schools plead for their share of the stronger students with the college training. All seem agreed, however, that the matriculate possessing the baccalaureate degree, other things being equal, is better fitted for entrance on medical study than the graduate of the high school.

NEW YORK ESSENTIAL STATUTORY REQUIREMENTS

The New York medical statute requires for admission to the licensing examination three essentials:

Educational.—1. Evidence of a general education preliminary to receiving the degree of bachelor or doctor of medicine in this state, the medical student certificate.

2. Evidence of the study of medicine for not less than four full school years of at least nine months each, including four satisfactory courses of at least six months each, in four different calendar years, in a medical school registered as maintaining at the time a satisfactory standard.

3. The degree of bachelor or doctor of medicine from some registered medical school.

The Principles of Registration.—The statute also requires that New York medical schools and New York medical students shall not be discriminated against by the registration of any medical school out of the state whose minimum graduation standard is less than that fixed by statute for New York medical schools.

All matriculates prior to Jan. 1, 1898, who graduated prior to Jan. 1, 1902, had to present evidence of three years' study of medicine in a registered medical school, subsequent to those dates, four years. And the earning of the medical student certificate two years prior to the date of graduation on a three years' course, when the majority of the strong schools were affording four-year medical courses, permitted the registration of most of the stronger medical schools of the United States.

For registration subsequent to Jan. 1, 1898, it soon became evident that but few medical schools of the United States could meet the New York statute if both preliminary and professional requirements were to be exacted of the school applying for registration. Under a ruling of the Attorney General, the registration by the regents of the general preliminary requirement, independent of the professional, seemed permissive. This permitted the registration of many of the stronger medical schools of the United States that formally agreed to meet the professional statutory requirements.

A widespread endeavor, however, to recognize the baccalaureate degree, as well as the degrees from schools of dentistry, veterinary medicine, pharmacy, osteopathy and the like, precluded the registration of a number of the stronger schools.

The Amendment of 1902.—After a careful discussion of the question by representatives of both the medical schools and of the medical profession of the state, an amendment to the medical act was passed in 1902, providing that:

"The regents may in their discretion accept, as the equivalent of the first medical year, evidence of graduation from a registered college course, provided that such college course included not less than the minimum requirements prescribed by the regents for such admission to advanced standing."

Meanwhile, as the amendment was passing through the legislature, it became apparent that the profession did not favor the extension of time to graduates of schools of dentistry, veterinary medicine, pharmacy, osteopathy, and the like.

THE DISCUSSION AT CONVOCATION, 1902

A careful discussion of this question in all its bearings occurred at convocation, 1902.[1]

This discussion was participated in by representatives of both the medical and the liberal arts faculties of representative New York institutions. In continuation of the study, a suggested outline was prepared and sent to many leading educators.

Results of Discussion.—For convenience, the theme was called the "Combined Baccalaureate and Medical Course," and it seemed uniformly agreed:

1. That the baccalaureate degree should meet the university ordinances now in force, i. e., be granted on four full years of collegiate work, subsequent to at least three years' high school preparation or the equivalent.

2. That the combined baccalaureate and medical course should consist of seven full years of baccalaureate and medical work.

3. That subjects the full equivalent of the present first medical year should be found in the college and high school course.

Discussion by Correspondence.—The first question on conclusion 3 was: Is there a practical unit of measure for the first medical year, or can one be determined? And the second: Can the medical schools readjust their curricula so as to admit to the second medical year graduates of registered colleges that present the full requirements of the first medical year, tested by that unit?

In order to determine whether the medical schools and colleges of New York state could agree on such a unit of measure, an outlined first medical year's requirements in anatomy, biologic sciences, chemistry, physics and physiology was carefully prepared by representatives of the medical profession and schools and sent to representatives of the independent medical schools to the universities maintaining both departments, and to independent colleges.

From the replies received, I quote the following representative of each:

President Stryker of Hamilton College, representing the independent colleges, writes: "As to our courses in the subjects named you will nowhere find more thorough college courses in the physical sciences And our teachers are strongly-equipped men, doing still work A student can have 353 hours in biology, exclusive of sophomore year, 235 hours in chemistry, and 198 hours in physics We can give a man all that is called for Surely, we meet all you ask"

---

* Read at the annual meeting of the Association of American Medical Colleges, Atlantic City, N. J., June 6, 1904.

[1] See Regents's Bulletin, No. 58.

President Wilson, Princeton writes "We do not here in Princeton believe in the principle of combining the baccalaureate and *medical courses* *We have not*, therefore studied out the proper details for such a combination '

Dr Raymond of the Long Island College Hospital representing the independent medical school through members of his faculty, writes "I can see no reason why the courses in physiology as now given in the L I C H can not be rearranged so as to harmonize with the plans suggested I approve of the course in anatomy as outlined I heartily approve of the plan outlined is a proper course in chemistry and physics"

Dr Albert Vander Veer of the Albany Medical College writes in answer to the question "Is the work too severe for the majority of the medical schools?' 'No 'Is the time devoted to instruction in laboratory work properly proportioned? "It is all right" "Can your medical school adjust its curriculum?' "It is going to be very difficult for us to arrange the subjects of anatomy and physiology but these are conditions that will arrange themselves in due time There must be a concession on the part of colleges as well as medical schools and this question will have to be studied with a great deal of care I admire the caution but firmness with which you are handling it"

President J G Schurman of Cornell University, representing an institution that maintains both faculties writes "It seems to me that there is more need of the extension of the course from four years to five than of the substitution of the work proposed '

Dean Polk of the medical faculty writes "You see that I would make the reason for shortening the course not the possession of an A B degree, which might mean anything or so far as medical study is concerned•nothing, but the previous mastery of the sciences embraced in the medical curriculum of the state of New York"

Dean Didama of Syracuse University writes "The full equivalent of the present first medical year can not be found in the college and high school course This university provides a joint baccalaureate and medical course of seven years If either course is to be shortened for the benefit of the other it should be the baccalaureate and not the medical"

Dean Richardson of Harvard University says "Students who can finish, or practically finish, the requirements for a degree in three years, which usually takes four, but prefer waiting until a later period for graduation may be admitted to this school with the understanding that their degrees will be received the following year"

Dean Smith of Yale says "The year's work is not too severe for any medical school to which college graduates would be likely to go The proportion of laboratory work is less than we devote to analogous subjects It does not seem practicable to change our curriculum"

Dean Charles H Frazier of the University of Pennsylvania writes "First-class medical schools, willing to admit students to their second year, should not regard the specified requirements as too severe The required hours of laboratory work are inadequate Three years ago this school recast its curriculum, adopting the 'semiconcentration' system"

Dean Vaughan of the University of Michigan says The year's work is not too severe for medical schools I do not think that the proportion between hours devoted to instruction and laboratory work is good I do not think it would be possible for a student having taken the course as outlined in some literary school to finish his medical work with us in three years'

Dean Dodson of Rush Medical College writes 'From the point of view of this institution it seems to me that your board has undertaken a difficult if not impossible, task'

Dean Ritchie of University of Minnesota writes "The work is not too severe for our school As laid down, it is not equivalent to the work done in our laboratories If we were inclined to admit the A B s to our second year, our state board of examiners would not permit it"

Dr Charles McIntyre of American Academy of Medicine says "I see no reason why it should be too severe for the majority of medical schools If the hours of lectures are supposed to be text-book work with recitations the ratio between the lecture and the laboratory work is a fair one It will require some readjustment of the medical curriculum"

These replies are samples that can be increased both in number and length

PROPOSITIONS

1 If credit is to be given to institutions without the state of New York more accurate registration, both of the college course and the medical course is essential To illustrate this proposition from the state board standpoint let me quote from a recent letter and its reply

Letter—Will you have the kindness to advise me by return mail as to your knowledge of the University of Sciences Francis Joseph at Kalozvar, Hungary, concerning the degree of Universal Medical Science?

Reply—It gives me pleasure to inform you that the Royal Hungarian University Francis Joseph is located at Klausenburg, Hungary, has a medical faculty of 12 full professors, an attendance of 106 medical students in 1901 02 The *program of actual* studies *for the doctorate calls for ten semesters* On completing the studies, candidates enter on three examinations for the doctorate, in the presence of a commisison composed of specialized professors, under the presidency of the dean of the faculty A candidate satisfactorily passing this examination receives the degree of Doctor Medicinæ Universæ Admission to the practice of medicine in Hungary is obtained at the end of the examinations for the doctorate, as in France, *and differs from* Germany, *where the state examination*, independent of the university examination, is obligatory

Let another testify concerning college degrees U S *Consul James H* Worman, Munich, *Bavaria*, writes regarding American academic honors

On the assumption of consular duties in Munich, in 1899, I *found* that American academic honors were a subject of general discussion in Germany So many German possessors of the American doctor title were illiterate persons that university men from our best institutions were looked at askance A careful inquiry into the whole matter soon disclosed a lamentable state of affairs in some states at home In the criminal history of the United States these cases will some day figure as evidences of official corruption of the most daring character Has not the time come for an earnest and united effort of the American colleges, the educational associations, state and national, and all other bodies interested in the good repute of American scholastic and professional institutions, to harmonious action in the states of our Union for such legislation that will bring the degree-conferring power under strict state supervision' A council of educators should be entrusted with powers similar to those vested in the regents of the University of the state of New York, this council to be composed of the most eminent men in the state without any reference to political considerations Further, that no degree conferring institution should be incorporated without the approval of this council of education In the self same spirit the legal section of the American Bar Association resolved, in 1897, that the degree conferring power should be subject to a strict state supervision to be exercised in a manner somewhat similar to that which is exercised by the regents of the University of the State of New York

The provision under the laws of New York to which these various propositions refer absolutely prevents any abuse by the academic or professional institutions of the state of their power to confer degrees

2 Accurate registration is dependent both on examinations and inspection

Pio A Da—— submitted a certificate from the University of Montevideo, Uruguay, to the University of ———, United States, and was admitted to the class of 1904 The certificate showed entrance examinations for admission to secondary studies and secondary subjects as follows

Algebra	3
First and second year French	6
Physics, parts one and two	4
Chemistry, part one	2
First and second year philosophy	3
Total, a year and a half in high school work	18

Consul Worman says, regarding the kind of legislation state boards should effect

> The authority vested in the inspector of education has in many states not been exercised on behalf of the professional schools and colleges Its exercise should be exacted of him by the profession in each state where such an official exists for the supervision of educational and professional institutions Where legislation is necessary to make the authority sufficiently abundant to suppress illegal acts by incorporated institutions, it should be urged by the profession without delay and with persistency Europeans, and especially the Germans, look on our whole educational fabric with distrust because of the swindling institutions that have been possible in certain states The courts, weary of distinguishing between the true and the false have ruled out all of them as private enterprises

To illustrate another phase of the necessity of accurate registration, dependent both on examination and inspection, I quote from another recent letter from a state of Australia

> The information furnished by you will be most useful to this board, and I am directed to convey the thanks of the members for your courtesy in the matter
>
> In future no application for registration from Americans who do not possess the certificate granted by your university will be entertained by this board Any British qualification is registerable in this state, but the board reserve to themselves the right of refusing to register any foreign qualification
>
> The rules regarding registration in the other states are practically the same, with the exception that no American qualifications are registerable in Queensland, and no foreign qualifications whatever in Western Australia
>
> I shall be glad if you will furnish me annually with a list of registered and accredited colleges of America for the guidance of this board

3 Reciprocity between states must be based on actual requirements met by licensees and a uniform minimum statutory requirement for all states of the Union is at present impracticable

To illustrate A practicing physician of the state of New York, having met requirements plainly above those of a neighboring state, was compelled by declining health to remove to that neighboring state to save her life She was dependent on her practice for her livelihood and could enter on a profitable practice if she could secure the requisite license The reciprocity clause of the statute in force in the state to which she would remove provided for reciprocity between states that conferred the same privileges on its licensees There was no question regarding her professional attainment She was denied the right to practice in the new state because the state from which she planned to move could not reciprocate the favor conferred on her by registration in the state to which she would have moved for the purpose of saving her life

4 State control should concern itself with the minimum statutory requirement for admission to practice, i e, the licentiate credential, and leave to the schools the determination of the maximum scholastic i e the degree

---

THE VALUE OF THE CONVERSATIONAL METHOD OF MEDICAL INSTRUCTION

THE 'STUDENTS' CONFERENCE'

JOSEPH McFARLAND, M D
Professor of Pathology and Bacteriology in the Medico-Chirurgical College
PHILADELPHIA

The methods of medical pedagogy have undergone many changes during the last twenty-five years, the most important being that the antiquated didactic method of teaching has in a large measure given place to practical clinical and laboratory teaching Some excellent authorities now advocate the complete abandonment of the didactic method, recommending that in its place certain text-book readings shall be assigned to the student, and that demonstrations and conferences between the teachers and pupils covering this subject-matter shall constitute the essential part of the instruction It has always seemed to me illogical to entirely do away with the didactic method, which I believe occupies an important and indispensable place in medical pedagogy, first, because there are many subjects that can be far better treated didactically than practically, second, because new and controversial matters can be far better summarized and treated by the professor whose business it is to familiarize himself with the advances of the subject than acquired by the student from text-books and third, because an enthusiastic and alert teacher can arouse the interest of his pupils by presenting his subject to them in a systematic, attractive and logical manner

I do not wish to be misconstrued to favor reversion to the didactic method exclusively I simply favor what I conceive to be an essential amount of didactic teaching, to be supplemented by work in the laboratory and by conferences

Nearly all of our ideas are based on opinion rather than on experience and it was with much interest that I availed myself of an unusual opportunity to demonstrate practically and statistically the value of the conference method of teaching

In the Medico-Chirurgical College of Philadelphia during the years 1903 and 1904 the sophomore class of the medical department was divided into two sections for practical work in the laboratories The section schedule was arranged in such a manner that during the first half of the college year one section remained unoccupied for one hour each week, and in the second half of the college year the other section was unoccupied during the same hour In order that his time should not be lost, I decided to utilize it for conferences

The sophomore students who were to receive this advantage attend two didactic lectures on general pathology each week throughout the college year, perform about 150 hours *practical work in the pathologic laboratory*, and about 80 hours practical work in the bacteriologic laboratory Two examinations were held during the year—one immediately after the Christmas vacation and one at the end of the course in the month of May

The division of the class into two sections was made according to their matriculation and the men of the two sections should have averaged about the same in their intellectual abilities

Section A was benefited by the conferences from the opening of the session to the mid-year examination Other than this there was perfect uniformity in the instruction received by both sections Forty-five men took the examination which was written and was a severe test carefully conducted The average mark attained was 82, the highest mark 98 the lowest mark 37 Taken by tens the marks ran as follows

100 to 90	16 men
90 to 80	12 men
80 to 70	7 men
70 to 60	6 men
60 to 50	men
50 to 40	0 men
40 to 30	1 man

In the same examination the men of section B, of whom there were forty-nine taking the examination and who had had *no conferences made an average mark of* 70 The highest mark attained was 100 the lowest 35 Taking this section by tens we find a striking difference which ran as follows

Between	100 and 90	there were	9 men
Between	90 and 80	there were	6 men
Between	80 and 70	there were	9 men
Between	70 and 60	there were	12 men
Between	60 and 50	there were	11 men
Between	50 and 40	there were	0 men
Between	40 and 30	there were	2 men

We thus find that the difference between the average mark attained by the men of section A who had conferences, and that of the men of section B who had none was 12 points in favor of section A This seemed to show how great an advantage the men gained through conferences, but the question, of course arose whether this was not an accidental difference depending on variation in the intellectuality of the two sections We notice, however, that the highest mark made in this examination—viz, 100—was made by a man in section B who had had no conferences, also that the lowest mark —35—was also made by a man in section B It is very striking that in section A, 16 men should receive marks above 90, but that in section B only 9 men should receive marks above 90, that in section A only 4 men should receive marks less than 60, but that in section B there should be 13

In order to make an accurate comparison between these sections, determine their comparative intelligence and ascertain whether the conference was the cause of the extraordinary variation in the marks, the questions in the final written examination of the year were arranged to cover only subject-matter that had been taught in the second half of the year By this means it will be observed that the results obtained by section A in its examination, covering a period during which its men had had conferences could be accurately compared with those of section B, covering the period and subject-matter on which its men had had the conferences

When we come to study the effects of the conferences on section B, as shown in this final examination, we find two possible sources of error, the first being that the final examination was a little more severe than the mid-year examination, and the second, that the men are apt to prepare more carefully for the final than the *mid-year* examination

Forty-seven men in section B took the examination, the average mark being 75 the highest mark 97 and the lowest 21

Between	90 and 100	there were	11 men
Between	80 and 90	there were	11 men
Between	70 and 80	there were	6 men
Between	60 and 70	there were	13 men
Between	50 and 60	there were	2 men
Between	40 and 50	there were	3 men
Between	30 and 40	there were	1 man

It will be noticed that the best man in this section who had received 100 at the trial examination, made only 97 at the final, and that the poorest man received 21 instead of 35 This seems to indicate that the final examination was more severe than the mid-year examination which will be borne out by subsequent demonstration The number of men receiving between 80 and 100 has increased to 22 over 15 in the mid-year examination, the number receiving less than 60 is 20, against 17 in the mid-year examination but the general average of the whole section has been raised 5 points This, taken by itself, is extremely suggestive, though not convincing, but when we turn to the results of section A in the final examination we are left no room to doubt the immense value of the conference method of teaching Of the forty-four men of section A taking the final ex*amination, the average mark was* 66, instead of 82, as in the mid-year examination The highest mark was 96, instead of 98 the lowest mark was 21 instead of 37

COMPARISON OF MARKS

	Final Examination	Mid year Examination
Between 100 and 90	5	16
Between 90 and 80	7	12
Between 80 and 70	8	7
Between 70 and 60	10	6
Between 60 and 50	7	3
Between 50 and 40		0
Between 40 and 30	2	1
Between 30 and 20	2	0

In the mid-year examination there were only 4 men with marks below 60, but in the final examination there were 14 The average intelligence of section A seems to have been a trifle greater than section B, for the average of all of the marks for section A in both examinations is 74 and the average of all the marks of section B in both examinations 72 5 The conferences during the last half of the year increased the average mark of the men in section B from 70 in the mid-year examination to 75 in the final examination, while section A, whose men attained a general average of 82 in the mid-year examination, lost an average of 16 points each, attaining a general average of only 66 in the final examination The final examination was more severe than the mid-year examination, as is shown by the fact that in the former the ninety-one men taking the examination made an average mark of 71, whereas the ninety-four men taking the latter examination made an average mark of 76

The total variation in the two sections, therefore, is determined by adding the loss of section A to the gain of section B, which equals an average of 21 points per man in favor of the men who had the conferences

It seems to me that no better demonstration of the value of a conference can be given than is shown by these statistics

Lest some one should misunderstand exactly what is meant by the term "conference" as here employed, it may be well to add a few words in explanation The class of students and the professor met in a small lecture room, and all sat down There is a certain pleasant informality about a seated professor that is wholesome on such occasions

A leading question was asked a student whose name was chosen from the list of the class, and by auxiliary questions the thoroughness of his understanding of the subject was brought out If it were shown by the answers that his knowledge was defective, another student was asked to point out the error In this manner, by asking a few students many questions and by permitting the students themselves to ask any number of questions, by immediately passing over matter that was understood and carefully explaining what was not understood, by endeavoring to determine why erroneous ideas were conceived, and by sound reasoning to bring the student's mind back to the correct channel of thought, the class progressed from day to day to a more and more thorough intelligence of the philosophy of the subject, so that they were easily able to cope with ordinary problems

---

THE ELECTIVE SYSTEM IN MEDICAL SCHOOLS

D N EISENDRATH, M D
Adjunct Professor of Surgery College of Physicians and Surgeons
CHICAGO

With the growth of the curriculum in our medical schools, the urgent necessity has arisen of either lengthening the number of years of medical study from four to five, or of so adapting ourselves to the needs of the medical student that some way must be found out of the difficulty

This increase in the number of subjects of study has arisen in two ways 1 The development of the various laboratory subjects (and by this I include anatomy, physiology, histology, chemistry and pathology) has necessitated the devotion of practically the entire first two, to so-called theoretical branches leaving the practical branch to the last two years 2 The rapid development of the special branches of both medicine and surgery (gynecology is included in the latter), has taxed the number of hours in the school year to the utmost An effort has been made in some schools to correct this latter growth, that is, practical branches, by dropping didactic lectures entirely and devoting the third and fourth years almost exclusively to demonstrations and clinical work at the bedside or in the dispensary, or hospital amphitheater Even with the latter change, the medical schools in our larger cities have found it impossible to give every student the necessary personal contact with both teacher and patient, which is the prerequisite of thorough medical education When we consider that the classes in our larger medical schools average from 150 to 200 in the junior and senior years, respectively it will be readily seen that the old-fashioned amphitheater clinics can no longer be profitable to either teacher or student I have stated above that we must find some way out of the difficulty and I am firmly convinced that the proper application of the elective system of our medical curriculum will solve this problem better than any other method In an article written by me two years ago I strongly advocated this system from a merely theoretical standpoint Since the publication of my article the elective system has been adopted by the college with which I am connected, and after one year's trial both faculty and students agree that it has been a great success The reason for this success has been that we have not applied the elective system without restriction It was thought by our faculty that the limited application of election on the part of the students would be of far greater value than if they were permitted to select both teachers and subjects without some guidance In the first place, we have applied the elective system to the third and fourth years only During the first and second years the student, as in other schools, takes up his anatomy, physiology, chemistry, materia medica, histology, biology, embryology, therapeutics, surgical pathology, hygiene and bacteriology, in a more or less routine manner, so as to get a thorough foundation for the more practical work of the following two years In addition to these laboratory subjects, elementary clinics, as they were called, were held by the professors of the third and fourth years twice a week When the students enter the third and fourth years they find the following schedule

JUNIOR YEAR

SPECIFIED REQUIRED SUBJECTS

		Hours
1	Neurology	72
2	Physical diagnosis	54
3	Dermatology	36
4	Principles and practice of surgery	144
5	Orthopedic surgery	36
6	Operative surgery	36
7	Laryngology rhinology and otology	36
8	Genito-urinary diseases	36
9	Clinical Anatomy	36
10	Microscopic and chemical diagnosis	66
11	Medical Jurisprudence	36
12	Autopsies	36
13	Dispensary clinics	54
		678

ELECTIVE SUBJECTS

1	Medicine (didactic work) lectures and recitations in four courses of 54 hours each Course A Infectious diseases and intoxications Course B Constitutional diseases and diseases of the kidneys Course C Diseases of the digestive organs Course D Diseases of the heart and lungs Total	216
2	Obstetrics	72
3	Gynecology	36
4	Medical amphitheater clinics	216
5	Neurologic amphitheater clinics	72
6	Surgical amphitheater clinics	180
7	Dermatologic amphitheater clinics	72
8	Laryngologic amphitheater clinics	72
9	Gynecologic amphitheater clinics	144
		1 080
	Total number of hours	1 758

SENIOR YEAR

SPECIFIED REQUIRED SUBJECTS

		Hours
1	Medicine	216
2	Psychiatry	36
3	Chest diseases	36
4	Pediatrics	54
5	Ophthalmology	18
6	Obstetrics	72
7	Gynecology	36
8	Autopsies	36
9	Dispensary clinics	54
		558

ELECTIVE SUBJECTS

1	Neurology	72
2	Surgery	72
3	Medical amphitheater clinics	252
4	Neurologic amphitheater clinics	72
5	Pediatric amphitheater clinics	72
6	Surgical amphitheater clinics	468
7	Ophthalmologic amphitheater clinics	108
8	Gynecologic amphitheater clinics	108
		1 224
	Total number of hours	1 782

In the junior year a total of 1 758 hours of instruction are offered and in the senior year a total of 1 782 hours Of this, 1,000 hours of instruction constitutes the year's work Each student is required to take all of the specified subjects in his year, in the junior year these subjects amount to 678 hours, the remaining 328 hours he can make up from the elective subjects, exercising to a large extent his own choice in the selection of subjects which he will take In the senior year the specified required subjects amount to about 558 hours, the remaining 112 hours may be selected from the elective subjects and clinics Even in this selection the student receives some guidance so that he must include among his elective subjects at least 120 hours of medical clinics and 120 hours of surgical clinics Clinics in diseases of the chest nervous system, pediatrics and dermatology are classified as medical At the time of registration the student is required to designate subjects which he elects in order to complete his 1,000 hours and will not be enrolled in the classes until his course has been approved by the secretary of the college The secretary has authority to refuse to approve of the course elected by any student when for any reason it seems to him not well selected

By a reference to the above table it will be noted that surgery is compulsory in the junior year but is elective in the senior year, and vice versa medicine, gynecology and obstetrics are elective in the junior year but are compulsory in the senior year

What are the benefits of this privilege of election on the part of the student? He can so adapt his time in both years that he will not be obliged to sit on the benches in the lecture room or in the clinical amphitheater from morning till night By a careful selection of clinical work he will have ample time to study and yet be able to have a full curriculum and not slight any subject -

In addition to this it gives the student more time to do special research work if he is prepared for this during his undergraduate period This power of election on the part of the students especially in the direction of clinical work, has had its reciprocal beneficial influence in all of the schools in which it has been applied on the faculty The moment a clinician is aware of the fact that the size of his audience is more or less directly dependent on his ability as a teacher he will make a greater effort to increase the same by a more careful study of his cases so that he will not be accused of being careless in his work He will acquire greater thoroughness in his surgical procedures Nothing acts as a greater stimulus to teachers than this elective system and once introduced, I am certain it will continue to find favor in every large medical school

In this manner a large number of students can find ample clinical and didactic work The college can also utilize to the best advantage all of its clinical facilities within its own walls or in hospitals contiguous to it At the same time, through this power of selecting where he wishes to take some of his clinical work, the abundant material which exists in hospitals and dispensaries at some distance from the main seat of learning can be used to the mutual advantage of the student and of the attending staffs of these extramural institutions

In my opinion, the elective system carefully applied is a stimulus to both teacher and student It enables a college with large junior and senior classes to so distribute its students that no clinic is overcrowded, and there is a resultant individualization which is not possible in large classes

THE TEACHING OF MATERIA MEDICA IN MEDICAL SCHOOLS

TORALD SOLLMANN, M D
Professor of Pharmacology and Materia Medica, Western Reserve University
CLEVELAND, OHIO

DESIRABILITY OF RESTRICTING THE COURSE OF MATERIA MEDICA

> I must confess, if I had my way I should abolish materia medica[1] altogether Not one trace of a knowledge of drugs has remained in my memory from that time to this, and really, as a matter of common sense, I can not understand the arguments for obliging a medical man to know all about drugs and where they come from Why not make him belong to the Iron and Steel Institute, and learn something about cutlery, because he uses knives?"
>
> "I entertain a very strong conviction that any one who adds to medical education one iota or tittle beyond what is absolutely necessary is guilty of a very grave offense"—Huxley, On Medical Education," 1870

Everyone will agree with this last sentence In most medical schools the required class attendance exceeds thirty hours per week, leaving the student a very insufficient time for home study This condition tends naturally to become worse, for the domain of medical knowledge is constantly extending and the teaching must follow these extensions It is, therefore, imperative to lighten the curriculum as much as possible by curtailing such studies as are no longer essential

A case in point is presented by the relation of pharmacology materia medica and therapeutics The study of the action of drugs by laboratory methods is a new branch and one which requires considerable time, which must be taken from some other subjects It is very true that a knowledge of pharmacology facilitates the study of therapeutics so greatly that a part of the time formerly devoted to therapeutics can be assigned to pharmacology without injury The saving thus effected, is not, however sufficient What further time is needed can be profitably drawn from materia medica (including pharmacy) if the course in these branches is wisely reorganized This can be readily done especially if they are taught in the same department as pharmacology as they should be, in my opinion

No one can doubt that the action of drugs is of vastly greater importance to the medical practitioner than their natural history The latter can only be of essential importance when the physician is located remote from a pharmacist a condition which is rather rare in this country Nothing prevents those who expect to be so situated from taking a special, optional course, and such should be offered by the college if it is needed Were there no other demand on the students' time, an exhaustive course of materia medica might be profitable to all other students, but there can be no question that the other demands are more important Indeed, I incline to the belief that the above advice of Huxley has not been sufficiently heeded by many schools doubtless because it is somewhat too radical

WHAT PARTS OF MATERIA MEDICA SHOULD BE RETAINED?

How far, then may the study of materia medica be safely curtailed? What is essential? What may be made optional and what omitted entirely? There is surely room for much honest difference of opinion in this connection I venture to give my views, as they may serve as a basis for reflection.

---

[1] It will I hope be understood that I do not include therapeutics under this head

I believe that the students should be given by way of introduction, some general ideas about the classes of chemical and structural constituents of drugs. Sufficient botany should have been learned in school and zoology is quite superfluous. The systems of weights and measures should be made thoroughly familiar. In regard to pharmacy, the student should learn the different classes of pharmaceutic preparations, their common characteristics and special uses and he should be given (by demonstration) a broad conception of how they are prepared. A little practice in simple dispensing is very desirable. All these data will be invaluable aids in understanding the materia medica of special drugs.

As regards the latter, only those should be discussed at all which have a real living therapeutic or toxicologic importance. Of the former the student should be required to know in the first place, those data which are needed in prescribing. The correct Latin name (faulty orthography indicates a faulty education in materia medica as elsewhere) the methods of administration the most useful preparations *and these only!*² Their dose solubility incompatibility and in a few cases their composition constituents should be taught only in so far as important therapeutically or by incompatibility.

Furthermore I believe that there should be required considerable familiarity with the appearance and other physical characters of the important drugs and their principal preparations so that the more common poisons may be identified or excluded. This seems to me very important and I believe that I lay rather more stress on it than is commonly done. The knowledge so obtained is also very valuable in that it often enables the physician to adapt the medicine to the peculiarities of the patient and sometimes to prevent the results of an error on the part of a druggist. I require this acquaintance rather oftener in the case of preparations than of crude drugs. I need hardly add that a good deal of discrimination must be exercised in selecting the drugs to be studied. The study must of course be made directly from the specimen.

It will be seen that the principal abridgment which I advocate in the teaching of materia medica concerns the number of drugs and preparations to be studied neglecting all those—and they are quite numerous—which are unimportant.³ A further saving is obtained by limiting pharmacy and by paying no attention to habitat natural order method of collection etc. These are quite useless for practical purposes, and those students who are interested in them can easily find the information. The natural orders are sometimes useful in explaining relationships but these can be touched on in pharmacology. In this way and by arranging the course as indicated below the class work in materia medica and pharmacy may be reduced to something like forty-five hours. Beside this required work I believe that a more thorough study of the chemistry of drugs and of pharmacy is very useful not so much by the direct knowledge which they give, but because the handling of drugs which they require gives a greater familiarity. This advantage is not sufficient, to my mind, to make them compulsory, but they may be offered as elective or optional work.

ARRANGEMENT OF THE INSTRUCTION

The dryness of materia medica is almost proverbial and it is, indeed, difficult to render interesting a study which consists so largely of memorizing. This difficulty is enhanced by constituting the subject into a separate course, as is so often done, and especially by letting this course precede that of pharmacology or therapeutics. What interest can there be for the student in memorizing certain tabulated information which he does not fully understand, about a drug which too often, he has never seen, and about the uses of which he has no clear idea? What opportunities I have had of observing have only confirmed my objections to this plan. I believe that only the preliminary subjects of pharmacy, etc. should be taught separately and that the materia medica of the individual drugs should be studied immediately *after* their action and uses. It is my practice to give the student his first experience with drugs by letting him use them in the laboratory, as this is the most efficient way of arousing his interest and showing him the importance of the drug. When he has in this way obtained an objective knowledge of the effects of most drugs and has become curious to have them explained their action is studied systematically in class and after each lecture the students are supplied with the specimens of drugs with instructions to describe them again objectively, in their notebooks. Around this nucleus the other information is grouped. In this way the interesting parts of the study carry the more mechanical parts so that these are less felt. It will be noticed that lectures are not emphasized in this schema. If there is any study in which formal lectures are misplaced this is certainly materia medica. The subject is taught with us almost purely by laboratory work and recitations.

DETAILS OF THE INSTRUCTION

The course of instruction in my department begins with a talk on the gross and histologic structure of drugs, illustrated by the demonstration of specimens and some thirty microscopic slides (two hours).' This is followed by chemic laboratory work on the important classes of plant constituents (two and a half hours). Then comes a demonstration on metrology (one hour) with a sufficient number of short drills. The general pharmaceutic methods (distillation percolation, etc.), are demonstrated as also the manufacture of the important classes of preparations tinctures fluid extracts, etc. (one and a half hours). The students are required to put up a series of prescriptions including pills, emulsions etc. (two hours). This subject is covered by about seven hours of recitation. Several topics are then taken up which do not interest us in this connection (incompatibility prescription writing toxicology). This brings us to special materia medica. The locally acting drugs are studied first so as not to anticipate the laboratory course.

I have already mentioned that the materia medica is studied in connection with the pharmacology. After hearing the lecture on a pharmacologic group of drugs the students are required to enter the important data of materia medica in a special notebook. This may be done in a separate laboratory hour or the lecture may be correspondingly shortened according to the number of drugs to be studied. The compilation of a special notebook has a number of advantages. It encourages the study of the specimens because correct descriptions must be given it can be made more concise than an

---

[2] There is some excuse for the pharmacopeia retaining obsolete drugs and preparations because these are sometimes used in certain localities or by the laity but there is no reason for burdening medical students with them. It is to be wished that all state boards would discourage such questions as "Give *all* the preparations of."

[3] This refers only to materia medica. It is often desirable to say a few words about the action of these unimportant drugs in the lectures on pharmacology.

text-book, and the mechanical act of writing, like drawing, is a powerful aid to memory

It is suggested (but not required) that the notebook be of quarto size, and that the information be entered under the following columns Latin name, English name, if of vegetable origin, the part of the plant used and chief constituents, appearance, odor, taste, mixable with water, with alcohol, dose, remarks (strength, etc, when asked for) The appearance, odor and taste should be described from the actual specimen All the important specimens for each pharmacologic group are exposed at a convenient place in the lecture room or laboratory, and left there until their study is entirely completed With large classes of students it would probably be convenient to have duplicate sets of specimens Each bottle should be labeled not only with the name of the drug, but also with the information whether it can be tasted freely with caution or not at all (I employ printed green blue and red labels for this) I also have the bottles labeled "important' or 'identification The latter are the specimens which the student must be able to identify at examination They comprise only those important drugs which may be readily recognized Those which would be difficult are merely marked "important" These the student must know so that when asked whether one of them *may* be such or such a drug (say potassium bromid) he can give an intelligent answer Colored illustrations of the more important drugs and herbarium specimens of the domestic medicinal plants especially those of toxicologic interest are also exhibited at the same time Unimportant drugs are not exhibited at all a notice being posted indicating where they may be found in the museum should anyone be interested

THE MUSEUM

The specimens in the museum should be arranged on the shelves by the groups in which they are studied All the important and identification specimens should be on one side of each shelf or it might be useful to have a duplicate set of these in a special case The curator may save himself considerable time by having the bottles numbered so that each will have a definite place, a laboratory boy can then replace them readily after they have been used The numbering may be done by the decimal system and a card index kept for instance Acid Salicyl 78 12, being found in case seven shelf eight twelfth bottle

I have had the cases constructed along the wall of the corridor leading to the laboratory, where the students are obliged to pass them frequently—on the supposition that they will, consciously and unconsciously, glance over the drugs The doors of the cases are kept unlocked

It will be seen the plan of teaching materia medica which I have adopted relies mainly on the individual exertion of the student The function of the instructor is limited to frequent short recitations, periodic inspection of the notebooks and occasional tests The latter are especially valuable for insuring an interest in the study

---

Resignation of Albert Fraenkel—Professor Fraenkel has been privat docent of internal medicine at Berlin for thirty years, and has borne the empty title of professor for the last fifteen He has now resigned these positions, weary of waiting, perhaps for the full rank of a professor He is a nephew and was an assistant of Traube, and is one of the most prominent investigators in internal medicine, especially in lung affections His lectures were very popular, especially among physicians taking postgraduate courses in Berlin

CLAY MODELING IN THE STUDY OF ANATOMY *

ARTHUR P HERRING, M D

Associate Professor of Anatomy, Baltimore Medical College

BALTIMORE

"It would be difficult to overrate the value of anatomic knowledge to every class of medical men, physicians as well as surgeons, and every one knows that this knowledge can never be acquired to any desirable degree of accuracy except by those who labor for it with the scalpel in their hands" This remark, made by Dr Samuel Chew in 1864, is especially applicable to the student of the present day Not alone is the scalpel necessary in order to comprehend the structure of the human body but the microscope, modeling, drawing, the study of serial sections, and other accessories must be utilized to make clear what to most students is a difficult and ofttimes an uninteresting subject Only one of the many helps in the study of anatomy will be presented in this

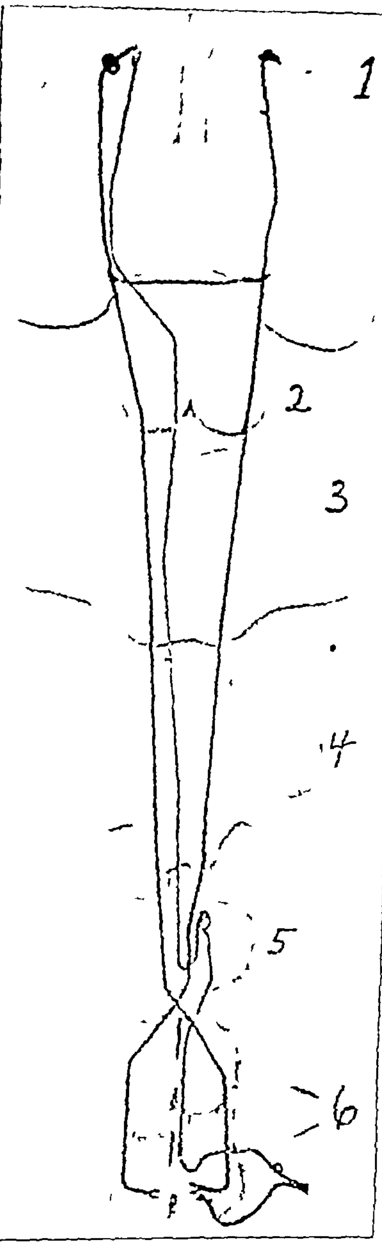

Fig 1—Motor and sensory conduction paths of the central nervous system, showing the peripheral and central neurons in a diagrammatic manner 1 Transverse sections of cerebrum 2 Mid brain 3 Pons 4 Upper medulla 5 Lower medulla 6 Spinal cord (Modeled by a member of the sophomore class)

paper, namely, the use of clay modeling in the study of anatomy

---

* Read before the Section on Neurology and Psychiatry of the Medical and Chirurgical Faculty of Maryland

The modeling of bones from clay was first practiced at the Johns Hopkins Medical School Since then it has been used at the Baltimore Medical College by Dr Sydney Cone in teaching osteology,[1] also at the University of Chicago[2] and at the University of California[3] At the latter school, Prof J Marshall Flint has used the method to record and preserve permanently the muscular variations found in the dissecting room[4] If this method is used in other schools I have not been able to find any report of the work

The method I wish especially to describe is the application of clay modeling to the central nervous system The study of the macroscopic and microscopic anatomy of the brain and cord has been very diligently pursued during the past decade, while the subject has received more attention in the college curriculum than heretofore The importance of teaching the subject to medical students can hardly be overestimated, as a thorough knowledge of the anatomy and physiology of the central nervous system lies at the foundation of organic nervous diseases Dr M Allen Starr in his recent text-book on "Organic Nervous Diseases," remarks "As the knowledge of the centers and tracts has grown as their location and action have been made clear, the meaning of symptoms previously perplexing has become plain" As a matter of fact, it is simply impossible to have a clear and concise picture of a disease of the nervous system without first understanding the structure of the part affected The ideal way to accomplish this result would be to study, first, the gross anatomy of the brain and cord, and, second, to make serial sections in the three dimensions, transverse, horizontal and longitudinal, stained by the Weigert-Pal method, and study them carefully, not neglecting, of course, the study of the nerve cell and the neuroglia by the various staining methods, as the Nissl, Bethe, Bende and many others

This necessitates not only a great deal of time, but also a vast amount of material and work In fact, it is not practical in the medical course as now arranged, and is really post-graduate work The best we may hope to do in the short time given this subject in most medical schools is to give the student a general idea of the subject and try to stimulate him to personal investigation after his college work is completed and he has time for research work

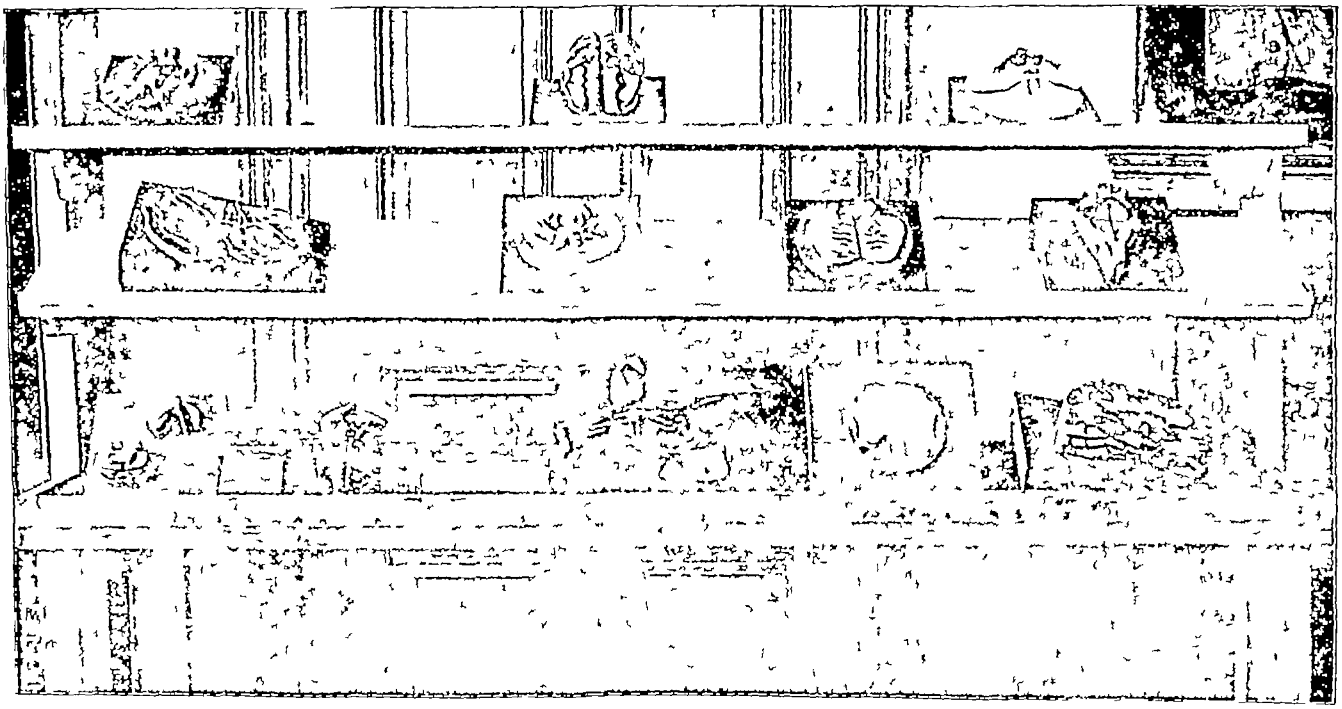

Fig 2—Modeling table on which are models made by members of the Class 05 Beginning with the upper row the first model on the right represents the base of the brain and cranial nerves 2 The cerebral hemispheres with fissures convolutions and motor areas colored 3 A horizontal section of the cerebrum, basal ganglia, internal capsule etc represented by various colors 4 (Middle row right side) A dorsal view of the medulla, pons and mid brain showing the fourth ventricle position of nuclei of cranial nerves funiculi of medulla etc 5 A transverse section of the pons the longitudinal fibers are elevated 6 A cross section of the mid brain the important structures are in relief 7 A transverse section of the upper medulla the arcuate fibers represented by various colors of floss olivary bodies nuclei etc raised 8 (Third row right side) A view of the mesial aspect of the left cerebral hemisphere 9 A cross section of the spinal cord gray matter in relief motor cells and tracts in different colors 10 A longitudinal section of the medulla pons and mid brain showing the position of the nuclei of the cranial nerves from the third to the twelfth and their superficial origin The nerve fibers are represented by floss 11 Ventral surface of medulla pons and mid brain 12 Superior and inferior surfaces of cerebellum Lobes and fissures in colors

The system of clay modeling tends to create an interest in this branch by presenting to the student's mind a realistic picture of a part that is otherwise very obscure when taught only from text-books or drawings It requires the men to think for themselves, to use their several special senses, and when molding the various specimens, form in their minds a number of impressions that otherwise would be received only through the auditory and visual pathways These multiple mental impressions serve to produce a lasting picture that will be easily retained Dr J Marshall Flint very forcibly states this idea in the following words "Every one apparently carries in his sensorium a very good stereognostic sense which is easily developed by a little training

To the student the advantage of the method lies in the

fact that he registers not only repeated visual images necessitated by the close study required to make a replica, but also utilizes his tactile sense and muscle sense as well The superiority of the modeling over drawing lies in the fact that arbitrary laws of perspective are not required, and the student has the advantage of having his record of the subject in three dimensions, just as it exists in nature"[5] The practice of sketching microscopic sections of the nervous system is, of course, a great help to the student, but it does not give him an idea of the part in three dimensions, a point that Dr Lewellys F Barker emphasized so strongly in his lectures on the anatomy of the nervous system at the Hopkins in 1898 The value of a reproduction of a part of the nervous system in three dimensions is beautifully shown in the Sabin model of the medulla[6]

The models made by the method advocated in this paper are at best crude, and are not to be compared to the artistic and realistic specimens produced by the Born reconstruction method[7] This latter method requires a great deal of careful and exact work and is hardly practical for the average medical student Bardeen speaks of this method as being "cumbersome and time-consuming" "Yet by no other method," he says "can so accurate an idea be obtained of the form of those structures which from their minuteness or complexity of relation, can not well be dissected out"[8]

The study of the central nervous system is confined as a rule to the sophomore year During the session Weigert-Pal specimens of the brain and cord are projected on a large screen before the entire class, and the minute anatomy described, models and drawings being utilized whenever necessary After the student has completed his dissecting he then begins to model certain portions of the central nervous system selected by the instructor The ordinary potter's clay is used The advantage of this kind of clay over the oil clay that is sometimes used, is that it hardens after a few days, when the models can be shellacked, colored and retained as permanent museum preparations, or kept by the students to study from if, however, it is desired to use the clay again, or keep it soft a longer time, it is easily accomplished by adding water to the clay and then kneading it well, or keeping a wet cloth over the model, which renders it pliable and easy to handle until the model is finished, when it quickly hardens again The models are made, not by being copied from stock preparations, but from actual gross specimens of the brain, which have been preserved in formalin, or, when modeling microscopic sections, showing the different tracts, etc, the student is allowed to refer to the drawing in the book or to the microscopic section under the dissecting microscope

Models of microscopic sections are generally enlarged two or three times and a definite proportion maintained throughout the series All important structures, such as the various tracts, the gray matter of the cord, the nuclei of the medulla and mid-brain, are elevated above the reticular formation To show the entire course of pathways different colored floss is used By this means the origin, course and termination of the various tracts is readily seen, as in Figures 1 and 3 The time usually required for the work varies from two to six weeks, depending on the facility with which the student completes the task

When the modeling is finished the instructor reviews the subject with each student and criticizes the models The best specimens are selected for the museum case, are uniformly colored, labeled and remain college property, thereby forming a valuable collection at a very nominal cost This also acts as an incentive for the students to do careful work, when they realize that their efforts are appreciated and their models, if good, remain as evidence of something real and substantial accomplished

[8] Loc cit

The real advantage of this method is that it serves to impress on the mind of the student information in a tangible and realistic manner It has been said that the knowledge that a man can use is the only real knowledge, the only knowledge which has life and growth in it and converts itself into practical power If this method does nothing more than stamp indelibly on the student's mind the essential facts of the structure of the nervous system, it will not have been used in vain The general idea obtained by this method will form a foundation for their future studies and on which a more elaborate superstructure may be erected

A PLEA FOR A STANDARD MEDICAL CURRICULUM *

GEORGE M KOBER, M D
Dean of the School of Medicine Georgetown University
WASHINGTON, D C

My experience as dean during the last few years impels me to make a strong plea for the unification of curricula in medical schools You, with other representatives of medical colleges, will recall the fact that the state medical examining and licensing boards differ widely in the minimum standard requirements for license to practice medicine, and no sooner have we adapted our curricula to the requirements of one state when we are confronted with another adjustment of studies to meet the demands of another state, and failure to do so means refusal of recognition of the school, and the holder of our diploma is not even permitted to appear for examination I venture to say that nearly every school had to make changes last year in order to comply with the requirements of the state of Michigan

We all admit that the problem of the medical university is to supply the community with competent medical men, and that it is the duty of the state examining boards to see that none but qualified men are licensed to practice one of the most difficult and responsible of all professions, hence the necessity of a reasonable standard of medical qualifications

Fortunately, we have adopted a minimum standard of preliminary education required for the study of medicine, and we should formulate a similar standard of medical education, based on uniform curricula

With a fixed minimum standard for admission, and a definite course of medical studies, with the prescribed number of hours of didactic and practical work in each branch, we may hope for a more uniform product, and if this product should reach the requirements of some of our best state examining boards, the way to reciprocity between the boards will be open, and much time and annoyance will be saved in the transfer of students from one school to another

A review of the examinations for medical licensure presented in a very able report by Dr Charles McIntire to the American Academy of Medicine May 11 1903 shows that during the year 1902 4 510 applicants were examined, of these 3,781 passed and 729, or about 16 per cent, failed The failures are not confined to graduates from indifferent schools, but include men from nearly every reputable school in this country, such as Harvard (1—117), Johns Hopkins (1—45), Columbia (9—173), Cornell (6—53), University of Pennsylvania (8—178), University of Michigan (9—77), University of Minnesota (2—86), University of Virginia (2—28), and Rush Medical College (6—232)

The conclusions to be drawn from such a result are 1, That our products are not up to the standard adopted by some of the state licensing boards, 2, that the applicants have deteriorated since graduation, 3, that in some instances the candidates have passed the college examinations by dishonest methods

A study of Dr McIntire's paper on "The Personal Equation in Examinations for Licensure," read before the American Academy of Medicine in 1902, demonstrates that the charge frequently made against state examining boards that they are too severe in their exactions is not true, for the returns of papers marked by college professors and members of such boards show a remarkable uniformity in this, that with hardly an exception the men who failed would not have been licensed by any of the boards or faculties making returns, and as a matter of fact the colleges were more severe in their markings than the boards But whatever the cause these painful facts confront us, and the sooner the subject is thoroughly investigated the better it will be for medical education and the ultimate welfare of our graduates I represent a small school, but should hail with delight any schedule of studies which would result in a well-rounded medical education, and I am sure every college represented in this association will cheerfully join in an effort to secure the desired end

It is not a simple problem, when we consider the widely divergent views entertained as to the best methods of teaching and the time allotted the study of various subjects, but it seems to me that we may profit by the experience of the older schools, and, without wishing to make any invidious comparison, I may say that, in the judgment of Major Borden, a very competent and discriminating observer, the most harmoniously educated candidates for admission into the Army medical corps were graduates from the University of Pennsylvania His judgment may be considered absolutely impartial for he is not an alumnus of that school, and was then as now a teacher in the school with which I am connected

How can we expect a harmonious product, when the very exhaustive report by Dr George W Webster, chairman of the Committee on Curriculum of the National Confederation of State Medical Examining and Licensing Boards, published in THE JOURNAL of the American Medical Association, Aug 15 1903, shows that the total hours vary from 5,000 in some to a little over 2,000 in other schools The time devoted to clinical instruction varies from 2,000 to a little over 200 hours, over 500 hours are devoted to the subject of chemistry in some schools, and less than half as many in others, anatomy varies from over 1,200 as a maximum to 200 as a minimum One school devotes over 400 hours to the study of physiology, while another has less than 100, medicine has over 1,200 hours in one and less than 200 in another In other schools such important subjects as physical diagnosis, pharmacology etiology and hygiene are not taught at all

Impressed with Dr Borden's observations and determined to profit by the experience of other schools a

---

*Read at the annual meeting of the Association of American Medical Colleges, Atlantic City N J June 6 1904 close examination of their method and the arrangement of studies was made and we have adjusted our curriculum accordingly

The demands of modern medicine are so exacting that the curricula in vogue fifteen twenty or thirty years ago in some of our best colleges no longer suffice to turn out a scientific physician, and I mean by that, a man who, because of his knowledge of the sciences on which medicine is founded has such a firm grasp and a clear comprehension of his subject matter as will enable him to become not only a successful practitioner, but also an intelligent student of progressive medicine

The foundation sciences of medicine are physics, chemistry biology, anatomy, bacteriology, physiology and pathology

A knowledge of physics as applied to medicine is essential as has been well said by Professor Vaughan in the application of all mechanical means for the correction of deformities for the treatment of fractures and dislocations for the study of errors of refraction, and in the use of the microscope ophthalmoscope, laryngoscope x-ray apparatus etc, and its general importance is appreciated by the leading medical universities of Europe It should be taught in the first year of the medical course We devote 10 hours to this subject We give 114 hours of chemistry in the first year half of which are devoted to practical laboratory work The time devoted to embryology, histology, osteology, general anatomy and physiology is shown by the table Materia medica very properly should be studied in connection with the biologic sciences during the first year

In the second year anatomy, physiology and chemistry including physiologic, medical toxicologic and sanitary chemistry are completed, and bacteriology pathology and pharmacology are begun, 24 hours are devoted to minor surgery

The student having acquired a fair knowledge of his foundation studies during the first two years, after additional instruction in pathology and physical diagnosis is now prepared to enter on the study of medicine surgery, obstetrics, gynecology, neurology and therapeutics, while a study of hygiene, which is the application of the laws of physiology, chemistry, physics, meteorology, pathology epidemiology and bacteriology to the maintenance of the health and life of individuals and communities, is not only necessary for the prevention, but also the cure, of diseases and serves the additional purpose of reviewing and applying the knowledge of the sciences just mentioned

All of the practical subjects, such as medicine, pediatrics, surgery, operative surgery obstetrics, gynecology, neurology and mental diseases, extend over a period of two years and are taught simultaneously to third and fourth year students both didactically and at the bedside

In the fourth year, in addition to the practical branches, we give our students special instructions in dermatology and syphilis, genito-urinary diseases, laryngology, rhinology, ophthalmology and otology military surgery, state medicine, morbid anatomy and medical zoology The course in medical zoology has special reference to the animal parasites in the human subject, supplemented by practical laboratory exercises in the microscopic examination of meat for trichinæ spiralis, and of feces for determining the presence of parasites, and we have found this course very helpful to our students and of extreme practical importance As a matter of fact, one of our graduates Dr Ashford was the first to demonstrate that the grave forms of anemias found in Porto Rico are due to uncinaria Americana, the hook-worm disease has been found by Dr Stiles to be quite frequent in our southern states, and we all know how frequently trichinasis is mistaken for typhoid fever

Our association was established for the purpose of promoting medical education, and yet, instead of leading others into the right path, we have been driven by the state medical examining boards and a strong public opinion, as manifested by the American Medical Association, to raise our standard of minimum requirements for admission into medical colleges New Hampshire, New York Pennsylvania, Ohio, Indiana, Illinois, New Mexico and Colorado practically demanded a higher standard long before we raised it, and, as a result, the diplomas of some schools are not recognized, and graduates from such schools can not appear for examination

More recently Illinois and Michigan have taken the initiative in establishing a minimum standard of medical education, and the example of these states is very certain to be followed by others in the near future If we wish to retain the confidence and respect of the American medical profession, it is our duty to equip our graduates in such a manner that their diplomas will not be discredited by any state in the Union, because, in the opinion of the board, the school granting it does not fulfill the established minimum standard of medical education Apart from the moral and ethical aspects of the question, however, I believe it will be in the highest degree good business policy to appoint a committee, which should co-operate with a similar committee appointed from the National Confederation of State Medical Examining and Licensing Boards, for the purpose of establishing such a standard

There are now 154 colleges in the United States Of these, 121 are regular and only 66 are members of the Association of American Medical Colleges The number of students vary from 6 to 1,047 in the different schools It seems to me that if the methods of teaching were more uniform the students would be more evenly distributed, which would be an advantage to students and schools alike There is much to be said in favor of small schools, where the number of students does not exceed 250, or from 60 to 70 in a class, as it enables each student to come into more intimate relation with the teachers in laboratory and hospital work and in connection with the system of recitations and conferences, which should be a part of the curriculum, makes instruction more personal and adapted to the special needs of the individual The time must come—indeed, it is close at hand—when the advantage of smaller classes will be appreciated, provided we are prepared to do honest and thorough work

It must be obvious that the reason some schools have too many students and others so few is due to the respective estimate of the relative merit in which they are held by the members of the medical profession, who are usually appealed to as referees by prospective medical students I can not agree with those who believe that there should be a different standard in different schools and who consider it a Utopian idea to expect that all the medical schools in the country should be based on a uniform curriculum any more than the various colleges or academies It seems to me that the standards of state boards are no higher for the graduates of these schools than for those of the smaller schools, all must possess the same qualification The subject of graduate work is another question There is, of course, no reason why schools engaged in turning out specialists and teachers should not vary their curricula with the special needs of the student

I realize that the weakness of our smaller schools lies not so much in the lack of funds or endowments as in the lack of methods It does not require expensive and pretentious buildings to do the work, but it does require competent men and proper laboratory equipment and clinical facilities

Fortunately, men always will be found in the profession willing to work in the interest of higher medical education, regardless of pecuniary reward My own school has no endowment whatever, it being the only school in Washington which abolished night sessions ten years ago, resulting as was anticipated, in financial losses, but we have the satisfaction of knowing that our product has improved We have only 140 students, but in spite of this we have equipped our laboratories and established a university hospital

The present cost of microscopes chemical, bacteriologic and physiologic apparatus puts them within the reach of every school A complete set of physiologic apparatus, sufficient for ten to fifteen students, can be purchased for $75 00 from the Harvard University four sets would be quite ample in a class of 40 to 60 students One microscope for every two students will answer very well until the funds will permit an instrument for every student, which, of course, is more desirable It goes without saying that no school should be permitted to enter our ranks unless it is properly equipped, and no school should give courses in junior and senior studies unless it has also suitable facilities for clinical teaching When this is done, will anyone deny that the school with 250 students will not turn out as good, if not a better, product than the large schools? How many times in our large schools is the average student called to the operating table to witness a cataract operation or abdominal section at close quarters, or to examine the patient before an operation and give to the professor and the class his opinion as to the pathology diagnosis and methods of treatment? What is true of the surgical is equally true of the medical cases

The time will come when all schools will be great, not in numbers, but in the quality of the product, and when this is accomplished I predict there will also be a leveling in the number of students The average American is too practical to travel thousands of miles when he can secure equal or possibly superior, advantages nearer home Another advantage from a purely business point of view will be the disintegration and abandonment of projected schools unwilling to bring their institutions up to a reasonable standard Who will patronize a school whose diploma is discredited by the majority of state examining boards, and who will dare to establish a new school unless fully equal to meet the requirements? If they should be established, the state boards will take such action as will prevent their doing any mischief

We do not need more schools, but we need better schools Every advantage is to be gained by the smaller schools from a uniform standard of curricula, and there is no good reason why we should not all survive in the face of an ever-growing and powerful nation, especially when there will be a more equal distribution of students with improved methods of instruction All had a humble beginning, but by perseverance and honest work we may hope to reach the same high plane of efficiency which some have attained Progress has crowned our past Let our conduct raise no blush on the cheek of posterity

Compulsory action is always to be deprecated, and yet this stares us in the face, on the other hand, much good can be accomplished by a joint deliberation between the colleges and the state boards of medical examiners, and the formation of a standard of medical education arranged in a logical order, specifying the minimum number of hours required in each study, and which will meet the views of the educator as well as the licensing boards

In order to comply with the requirements of the Michigan State Board of Examiners, we have arranged a schedule for the Medical School of Georgetown University, which is at least suggestive

It will be seen that the requirements do not differ materially from the average obtained in 43 medical colleges in the United States, and is really in excess of the standard curriculum recommended by a special committee of the National Confederation of State Examining and Licensing Boards, which places the minimum requirement at 3,600 hours

The requirements of the Michigan State Board of 4,240 hours may be considered excessive, and might with advantage be reduced to 4,000 hours, devoting about 950 hours to each of the first two years' work and 1,150 hours each to third and fourth year work

I have purposely devoted less time to freshman and sophomore studies, as the acquisition of the sciences taught during the first two years really involves more of a mental strain than the work of the third and fourth year

CURRICULUM AT THE SCHOOL OF MEDICINE GEORGETOWN UNIVERSITY

Based on the 4 200 hour standard prescribed by the Medical Examining Board of the State of Michigan in force during the session of 1903 1904

	Lecture	Laboratory work	Total
First Year—			
Physics	20	20	40
Chemistry	72	72	144
Osteology	24		24
Anatomy	150	180	330
Histology	24	100	124
Embryology	85	50	85
Physiology	75	40	115

CONCLUSION

In conclusion let me reiterate that I represent a small, struggling medical school and if I differ from the views expressed by others, I do so with great hesitation Apart from the ethical aspect and the imperative demands for reform throughout the medical profession I consider it in the highest degree good business policy to advocate a plan which will improve the quality of the product and equalize the number of students a result which can not fail to be acceptable to the larger schools and extremely profitable to the smaller schools and I therefore beg to offer the following resolution

Resolved That a Committee on National Uniformity of Curricula be appointed to co operate with a similar committee appointed by the National Confederation of State Medical Examining and Licensing Boards for the purpose of presenting a minimum standard of medical education together with such recommendations as the committee may deem proper as to the division of the subjects in a four year graded course Said report to be presented at the next annual meeting and to be printed and distributed at least one month before said meeting

CASE OF TETANUS SUCCESSFULLY TREATED BY ASPIRATION OF THE CEREBROSPINAL FLUID AND INJECTION OF MORPHIN-EUCAIN AND SALT SOLUTION

JOHN B MURPHY A.M , M D
CHICAGO

History—Alex S , aged 8 years, was admitted to Mercy Hospital July 10, 1904 He is one of eight *healthy children* and has had no previous illness Seven days preceding admission while crossing a dirty street, he stepped on a piece of glass, cutting his foot in two places He received no medical treatment, except that the foot was washed by his father and applications made of a lotion and of antiphlogistin This was prescribed by a physician without seeing the case Five days later (six days after the accident) stiffness of the jaw began and he was seen for the first time by a physician At this time he had had for twenty four hours pronounced trismus, and spasm of the muscles of the neck, with occasionally contraction of the muscles of the back, but not severe There had been no chills fever nor sweats There was little redness or irritation around the wounds

Hospital Examination—When admitted to the hospital there was a wound one inch and a half long on the outer aspect of the anterior portion of the foot, and a smaller wound on the inner side near the heel The trismus was pronounced and every three to five minutes there was contraction of the muscles of the back with pronounced opisthotonos

Surgical Treatment—The patient was anesthetized The anterior wound appeared healed, but on separating the edges a piece of glass and some debris were found in it A smaller piece of glass with pus was found in the posterior wound These had been there for seven days The pus was examined for tetanus bacilli and none found, an anaerobic culture was made with no result. The wounds were curetted, cauterized with a 95 per cent solution of carbolic acid and packed with iodoform gauze The patient slept a short time after the anesthetic Then the convulsions came on every ten to fifteen minutes and lasted one to three minutes His temperature was 99 8 degrees, pulse 110

Treatment by Antitetanic Serum—On July 11 he was given three full doses of antitetanic serum, without effect The convulsions increased in frequency and were almost continuous

Treatment by Morphin Eucain Injections—On the morning of July 13 a lumbar puncture was made and 16 c.c of cerebrospinal fluid withdrawn It was cloudy in its appearance to the naked eye At the same time through the needle 3 c c of the following solution were injected into the subarachnoid space

R	B eucain	gr iss		00
	Morphin sulphate	gr 1/3		02
	Sodium chloridi	gr iii		18
	Distilled water	℥iiss	105	

This had been sterilized by boiling The patient slept four hours immediately following the injection and through the night slept an hour and a half at a time The spasms were of shorter duration and he had only eight in the succeeding twenty four hours His temperature the evening of July 13 was 102 degrees and his pulse 120

Course and Recovery—On July 14 a spasm occurred at about 4 a m which was the most severe he had had since the injection At 11 a m another puncture was made and 15 c c of fluid withdrawn This looked comparatively clear Four c c of the above solution were again injected He slept four hours following this injection Pulse was 100, temperature 100 degrees He had eight spasms between this and noon of the following day, July 15, when they began to increase in frequency The spinal canal was again punctured 15 c c of fluid withdrawn and 4 c c of the morphin eucain solution injected He had no spasm until late in the afternoon and only an occasional mild spasm through the night. At noon July 16 15 c c of fluid were withdrawn and 4 c c of the solution injected

July 17 his condition was so good that no injection was made In the night the spasmodic contractions again occurred and by the next morning they were being repeated every hour though of mild severity He could now talk well and had had a good night's rest On July 19 the usual aspiration and injection were made. On July 20 he had a few very mild spasms

On the morning of July 21 the spasms were a little more severe although at intervals of three or four hours At noon there was another aspiration and injection made Following this there was no spasm, his condition improved the trismus gradually subsided and he was discharged cured July 31

THE DOSAGE

It will be noted that the quantity of morphin in each injection was 1/75 of a grain, and of eucain 3/50 of a grain These were extremely small doses, and as it was my first case I feared to increase the quantity There was no sweating headache nor collapse symptoms so frequently noted after injections of cocain for spinal analgesia It will be recalled that at the time cocain was first used for analgesic purposes it was believed the injection of any solution in the spinal canal would produce these symptoms The injections immediately relaxed the spinal muscles, and they remained relaxed for considerable periods of time, hence the patient had a good opportunity to sleep and rest from the time he received the first injection It is my belief that the strength of the eucain portion of the solution should be increased so the patient would receive 1/6 or even 1/3 of a grain with each injection Furthermore that the aspirations and injections might be repeated with greater frequency There seemed to be no ill effect from the withdrawal of the fluid, and after the third day the fluid showed no polynuclear leucocytes

SUGGESTIONS FOR FUTURE CASES

I believe eucain is much safer than cocain, first, because it admits of boiling for sterilization, and second. because there is less idiosyncrasy to intoxication As these patients die, many of them from exhaustion from the spasms, and some from the severity of the spasms of the respiratory muscles themselves, I feel that this can be entirely overcome with the injections I have not had an opportunity to try it on other cases, and publish this merely as a preliminary report—as this is the season in which tetanus is most frequent—that others may be induced to try it I do not know whether the benefit was attributable to the extraction of the cerebrospinal fluid or to the injection of the solution, or both The fact the fluid withdrawn on the first, second and third days contained pus, and after that none, would lead one to believe that possibly the diminution of pressure in the cerebrospinal cavities aided the fluid in overcoming the infection, just as in epidemic cerebrospinal meningitis, repeated spinal puncture relieves the pressure and gives the greatest percentage of recoveries

There is no reason why the cerebrospinal cavities cannot be washed out in severe infections with salt or other neutralizing solutions by the following method which I shall put into practice in the first case of cerebrospinal meningitis coming under my observations First, make a drill puncture of the cranium over the lateral ventricle, insert a fine needle until the cerebrospinal fluid escapes, second, insert a needle into the spinal canal in the lumbar region and allow a normal salt solution to flow, under hydrostatic pressure, from the needle in the right ventricle down through the foramen of Magendie and the spinal canal, to, and out of the needle in the lumbar area This can be accomplished on the cadaver, as I have demonstrated Permanent drainage of the cerebrospinal canal has been almost uniformly fatal and should not be instituted

THE UNITED STATES PUBLIC HEALTH AND MARINE-HOSPITAL SERVICE

PART I A HISTORICAL SKETCH

(*Continued from Page 408*)

(C) DR HAMILTON'S ADMINISTRATION (1879 1891)

In 1879 Surgeon-General Woodworth died, and was succeeded by Surgeon John B Hamilton The new head of the service vigorously pursued the policy inaugurated by his predecessor in office The regulations were revised and brought up to date, embodying the substance of circulars and orders issued since 1873 Stricter accountability for public property, improved discipline greater amount of relief furnished at a relatively less cost, and greater accuracy in the medical statistics were the objects attained by rigid enforcement of regulations

During the first four years of Dr Hamilton's administration the National Board of Health, created by the law of 1879, was in active existence, and the public-health work of the service did not increase in consequence The law under which the National Board of

---

EDITOR'S NOTE.—This article began July 30 The Army Medical Department was discussed May 7 14 21 28 and June 4

Health operated expired by limitation, June 2, 1883, and the Marine-Hospital Service took charge of national quarantine and public-health matters under the quarantine law of 1878, which then became operative A contingent appropriation was made by Congress for the prevention of the introduction and spread of epidemic diseases and the maintenance of quarantine at points of danger This appropriation supplied the necessary funds for quarantine and epidemic work, which the quarantine law of 1878 failed to provide

In 1881 the assignment and collection of the hospital tax from seamen was abolished, and the same act provided that "the expense of maintaining the Marine-Hospital Service should hereafter be borne by the United States out of the receipts from duty on tonnage provided for by this act, and so much thereof as may be necessary is hereby appropriated for that purpose '

In January, 1886, Surgeon-General Hamilton reresumed the publication of the "Weekly Abstract of Sanitary Reports," as required by the act of 1878, which had been temporarily suspended during the activity of the National Board of Health

The quarantine stations which were established by the National Board of Health were mainly refuge stations and when the service took charge of these in 1883, their equipment was deficient Surgeon-General Hamilton recommended that "the national quarantine stations be made permanent, and that they be equipped with all the necessary appliances known to modern sanitary science for the treatment of infected vessels and their cargoes, so that not only may immunity from the importation of contagious diseases be secured at those stations, but such security be had with the least possible obstruction to commerce" In 1888 a law was passed perfecting the national quarantine system on the Atlantic and Gulf coasts, and providing for the establishment of three stations on the Pacific coast An appropriation of $500,000 was made to carry out the purposes of this act

During the first year of Surgeon-General Hamilton's administration, the Secretary of the Treasury issued a circular which specified that all persons applying for either renewal of license or original license as pilots of steam vessels should be required to undergo a visual examination, to determine the presence or absence of color blindness, and that the examination should be made by a medical officer of the Marine-Hospital Service, whose certificate of good color sense should be essential to the issuance of a license

Surgeon-General Hamilton provided a "Handbook for the Ship's Medicine Chest," for the guidance of masters of vessels carrying no doctor Section 4569 of the Revised Statutes compelled the carrying of a medicine chest by such vessels, but neither specified what the contents should be nor provided instructions for its use This "Handbook" supplied the deficiency, gave lists of necessary medicines, and in simple language directed the masters what to do when skilled medical assistance was unobtainable

During this period the medical officers were required to report not only on the sanitary conditions of their hospital, but also on existing conditions in the cities in which they were stationed The hygiene of the merchant marine continued to receive the attention of the service, and from the control of outbreaks of smallpox or other contagious disease among sailors especially on western lakes and rivers, it was but a short stride to the supervision of local epidemics and the prevention of their spread

The service assisted the local authorities in controlling the epidemics of yellow fever in Florida and Texas in 1882, and in all subsequent epidemics have succeeded by the detention camp in preventing the spread of the disease without resorting to 'shotgun' quarantine

The first detention camp was established (1888) on the south bank of St Mary's River (the boundary between Georgia and Florida), and was called Camp Perry Refuge camps near infected cities were not new but an inland quarantine where suspects were detained only long enough to demonstrate that they were not infected and then permitted to proceed north was a novel procedure at this time

In 1889 the Secretary of the Treasury detailed Surgeon-General Hamilton to attend the Sixteenth International Medical Congress at Berlin, Germany, and to study European hospital construction The surgeon general visited may large European cities, studied their hospitals, and made an exhaustive and critical report on the systems employed in their construction

The regulations of the service since the reorganization required that all applicants for the service should be examined by a board of officers, and appointed to the lowest grade, that of assistant surgeon The examinations were severe and the standard of excellence demanded was high, and in consequence 80 per cent of the applicants were rejected The surgeon general considered statutory provision confirming the regulations on this point necessary for the maintenance of this high standard of excellence, and in 1889 Congress enacted that, after passing a satisfactory examination before a board of service officers, the applicant was to be commissioned by the President by and with the advice and consent of the Senate, appointment to the service to be made only to the lowest grade that of assistant surgeon

Assistant surgeons were to be promoted to the rank of passed assistant surgeon after four years' service and the passing of an examination, and promotion to the rank of surgeon only after due examination

To provide additional protection to the country at large in preventing the spread of contagious disease from one state or territory to another, the interstate quarantine law of 1890 was passed by Congress In June 1891, Supervising Surgeon-General Hamilton resigned, and was succeeded by Surgeon Walter Wyman who was then chief of the quarantine division

Clinical Report.

A CASE OF BRASS MOLDER'S AGUE

STEPHEN R PIETROWICZ, M D
Attending Physician to St. Mary s Hospital
CHICAGO

Patient—J G, aged 33 years, Polish, married, brass molder, has been under my personal observation one year He entered St. Mary s Hospital July 17, 1904

Family History—Father and mother died of old age, disease unknown to patient Two brothers and two sisters alive and healthy, one brother died of some acute abdominal affection

Personal History—Measles and scarlet fever as a child, otherwise well until present illness No venereal history

Present Illness—Patient came to this country fourteen years ago and began working at an occupation in which he continually inhaled and was exposed to an atmosphere laden with minute particles of brass filings One year later his symptoms began He first noticed palpitation of the heart, accompanied by pain in precordial region, also pain in abdomen of a dull character, sometimes lasting several hours Numbness and cramps in arms and legs, together with difficulty in moving the extremities were not infrequent phenomena A prominent symptom was a fine tremor, most marked in muscles of the face, hands and fingers On several occasions he had distinct chills lasting several minutes Constipation was very obstinate requiring cathartics constantly Patient's appetite gradually became impaired He was troubled with bronchitic symptoms which were severe From time to time he was confined to bed for periods of one or two weeks Recently severe headache, attacks of vertigo and dizziness and a burning sensation in the epigastric region has been noticed His hair has fallen out lately and his memory is failing As to habits, he is a habitual user of alcoholic beverages, which he thinks aggravate his condition, he does not use tobacco in any form

Examination—Medium sized man, height 5 feet 6½ inches, weight 126 pounds, emaciated, sallow, anemic, unhealthy looking complexion, has lost 25 pounds in the last month Marked baldness of head, also some loss of both pubic and axillary hair Tongue coated heavily, foul breath, shows a beautiful green zone or border along the gingival margin of the gums, which can not be removed by ordinary scraping Teeth in good condition Pupils react to light and accommodation, eye grounds normal Skin tinted yellow, dry, scaly Sensation normal, electrical reaction normal Patellar reflexes exaggerated, especially on right side, where there is a repeated clonic response to a moderate tap Ankle clonus present in both Cremasteric and corneal reflexes normal Fine tremor in fingers, hands and facial muscles, also wasting of said muscles, speech indistinct and tremulous No glandular enlargement, osseous system negative Arteriosclerosis marked Lungs slightly emphysematous Heart, liver and spleen normal Abdomen negative, some epigastric tenderness and a loose tenth cartilage

Urinalysis—Negative, Marsh test negative Examination of feces, chemical and microscopic, negative.

Examination of Blood—Differential count of 120 fields

Hemoglobin		80 %
Red cells		4 960 000
White cells		10 800
Small lymphocytes	110	18 %
Large lymphocytes	65	10 %
Eosinophiles	10	016 %
Polymorphonuclear leucocytes	400	66 %

Treatment—At the beginning the patient was treated symptomatically, iodid of potassium in a saturated solution was given until physiologic reaction appeared The literature was scanned, but without giving much information Milk given very hot, but not boiled, afforded a good deal of relief It was given with the idea that it would precipitate both zinc and copper into insoluble albuminates No marked improvement followed the use of bromids and iodids During the acute attacks morphia in ½ to ¾ gr doses was administered hypodermically with only slight cessation of pain Quinin hydrochlorate and sulphate were given for the chills without effect The patient was given large doses of zinc phosphid and sulphate of strychnia for the tonic effect On his entering the hospital it was discovered that anything hot was soothing to him and relieved his pain, hot water was then tried, to which was added gum camphor, 5 grains to a pint of hot water, he would drink at times two to three pints of this with great relief The local application of a large mustard plaster over the entire abdomen gave relief at times Total abstinence from all meat was followed by improvement, and he has since been put on a strictly vegetable diet, with no return of symptoms It is strange that hot water with small doses of camphor gum should give relief It is worthy of a trial

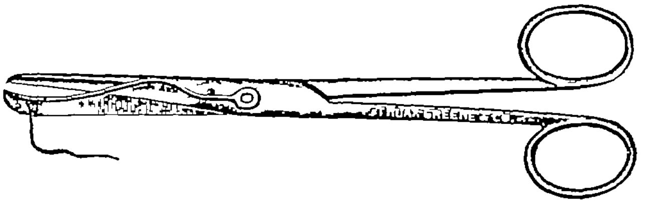
New Instrument.

SUTURE SCISSORS AND SUTURE REMOVER IN ONE INSTRUMENT

A. E BENJAMIN, M.D
Clinical Instructor in Gynecology College of Medicine and Surgery University of Minnesota
MINNEAPOLIS

It is customary for a great many surgeons to stitch up lacerations of the cervix with non absorbable sutures, such as silkworm gut Lacerations of the perineum are more frequently sewed up with such material When such sutures are used it is often difficult to remove them The reasons for this are obvious 1 Sutures within the cervix are deeply situated, 2, there is usually not sufficient light, 3, sutures occasionally are buried beneath congested, inflamed or overlapping tissue, 4, there is very little room to work, 5, it is difficult to use two instruments within the vagina, viz, one to hold the end of the sutures, and the scissors to cut the sutures, 6, the view is obstructed so that it is difficult to secure the suture without wounding the portio vaginalis A few of these difficulties are experienced in removing perineal sutures

It occurred to me that a combined instrument might be made so that the sutures could be hooked up, cut and withdrawn, all with the same instrument Such an instrument I have had constructed. It consists of an ordinary 7 in straight scissors, with a hooked point on the lower blade On the flat side of this hooked point is fastened a block of steel about 1/16 of an inch wide, corresponding with the curve of the hook, extending ½ of an inch along the flat surface of the lower blade, and fastened a little below the level of the cutting surface The hooked point is rounded and dulled so that it will not wound the soft tissues A spring, extending to the point of the upper blade, is fastened by the screw holding the two blades It has a surface at its extremity to correspond with the curve and width of the block on the lower blade. Two pins a little in front of the screw, hold the spring, making it firm above and below The opposing surface of the spring and block are roughened so as to hold the suture firmly This is more necessary for silk sutures A suture that is to be removed is caught up with the hook, the scissors closed, and the spring clamps the suture onto the block before the cutting surface of the blades sever the suture. When the suture is cut, traction is made on the scissors, this pulls the suture out of the tissues Care should be observed to get the knot on the side of the spring These scissors can be used for removing sutures from any locality, but will be found especially useful in removing sutures located deeply, as within the cervix



The advantages for such an instrument are that one hand is used, and thereby the view is not obstructed, the sutures can be caught up with the hook quickly cut and removed

Clinical Report.

A CASE OF BRASS MOLDER'S AGUE

STEPHEN R PIETROWICZ, M D
Attending Physician to St. Mary's Hospital
CHICAGO

Patient—J G, aged 33 years, Polish, married, brass molder, has been under my personal observation one year He entered St. Mary's Hospital July 17, 1904

Family History—Father and mother died of old age, disease unknown to patient Two brothers and two sisters alive and healthy, one brother died of some acute abdominal affection

Personal History—Measles and scarlet fever as a child, otherwise well until present illness No venereal history

Present Illness—Patient came to this country fourteen years ago and began working at an occupation in which he continually inhaled and was exposed to an atmosphere laden with minute particles of brass filings One year later his symptoms began He first noticed palpitation of the heart, accompanied by pain in precordial region, also pain in abdomen of a dull character, sometimes lasting several hours Numbness and cramps in arms and legs, together with difficulty in moving the extremities were not infrequent phenomena A prominent symptom was a fine tremor, most marked in muscles of the face, hands and fingers On several occasions he had distinct chills lasting several minutes Constipation was very obstinate requiring cathartics constantly Patient's appetite gradually became impaired He was troubled with bronchitic symptoms which were severe From time to time he was confined to bed for periods of one or two weeks Recently severe headache, attacks of vertigo and dizziness and a burning sensation in the epigastric region has been noticed His hair has fallen out lately and his memory is failing As to habits, he is a habitual user of alcoholic beverages, which he thinks aggravate his condition, he does not use tobacco in any form

Examination.—Medium sized man, height 5 feet 6½ inches, weight 126 pounds, emaciated, sallow, anemic, unhealthy looking complexion, has lost 25 pounds in the last month Marked baldness of head, also some loss of both pubic and axillary hair Tongue coated heavily, foul breath, shows a beautiful green zone or border along the gingival margin of the gums, which can not be removed by ordinary scraping Teeth in good condition Pupils react to light and accommodation, eye grounds normal Skin tinted yellow, dry, scaly Sensation normal, electrical reaction normal Patellar reflexes exaggerated, especially on right side, where there is a repeated clonic response to a moderate tap Ankle clonus present in both Cremasteric and corneal reflexes normal Fine tremor in fingers, hands and facial muscles, also wasting of said muscles, speech indistinct and tremulous No glandular enlargement, osseous system negative Arteriosclerosis marked Lungs slightly emphysematous Heart, liver and spleen normal Abdomen negative, some epigastric tenderness and a loose tenth cartilage

Urinalysis—Negative, Marsh test negative Examination of feces, chemical and microscopic, negative.

Examination of Blood—Differential count of 120 fields

Hemoglobin		80 %
Red cells		4 060 000
White cells		10 800
Small lymphocytes	110	18 %
Large lymphocytes	65	10 %
Eosinophiles	10	016 %
Polymorphonuclear leucocytes	400	66 %

Treatment—At the beginning the patient was treated symptomatically, iodid of potassium in a saturated solution was given until physiologic reaction appeared The literature was scanned, but without giving much information. Milk given very hot, but not boiled, afforded a good deal of relief It was given with the idea that it would precipitate both zinc and copper into insoluble albuminates No marked improvement followed *the use of bromids and iodids During the acute at*tacks morphin in ½ to ¾ gr doses was administered hypodermically with only slight cessation of pain Quinin hydrochlorate and sulphate were given for the chills without effect The patient was given large doses of zinc phosphid and sulphate of strychnia for the tonic effect. On his entering the hospital it was discovered that anything hot was soothing to him and relieved his pain, hot water was then tried, to which was added gum camphor, 5 grains to a pint of hot water, he would drink at times two to three pints of this with great relief The local application of a large mustard plaster over the entire abdomen gave relief at times Total abstinence from all meat was followed by improvement, and he has since been put on a strictly vegetable diet, with no return of symptoms It is strange that hot water with small doses of camphor gum should give relief It is worthy of a trial

MEDICAL EDUCATION IN THE UNITED STATES

The present issue of The Journal is the fourth annual educational number, and contains statistics regarding medical education in the United States, covering the year ending June 30, 1904 The information contained in this statistical study was obtained largely from the colleges directly, and has been certified to by some one in authority in each school, so that we have every reason to believe that all the data are as correct as can be obtained It has been no easy task to gather all this information, and any errors that may have crept into the work are only such as are likely to occur when information is gathered from many sources Only one college in the United States (not including the Manila and San Juan schools) flatly refused to give any information, but the data which might have been obtained would not have changed the totals appreciably We take this opportunity of extending our thanks to all those who aided us in gathering these statistics

A perusal of our study will show that medical education, so far as students and colleges are concerned, has not changed materially during the past year, although a slight improvement is noticeable in the advances made in the length of the college term This improvement is, on the whole, very gratifying, inasmuch as it shows the disposition of all the schools to better medical education In the statistics contained in this number, we have embodied some new features which, we are convinced, will be of interest to medical educators

Number of Medical Students —The number of medical students in the United States for the year ending June 30, 1904, was 26,138—a decrease of 1,477 below the year 1903 Of this number, 23,662 were in attendance at the regular schools, 1,105 at the homeopathic, 1,014 at the eclectic, and 357 at the physiomedical and nondescript schools There was a decrease in the attendance of the regular schools of 1,268 below last year, and a decrease of 1,216 below the year previous—1902 In the homeopathic schools, there was a decrease of 393 below that of 1903, and a decrease of 512 below 1902 The eclectic schools have been increasing steadily since 1900 In 1904, 1,014 students attended the eclectic schools, an increase of 166 over the attendance of the year previous—1903 The physiomedical and nondescript schools show an increase in attendance of 18 over the previous year, the attendance in 1903-04 being 357 This increase, however, occurred in the nondescript schools and not in the physiomedical

Table of Medical College Attendance

Year	Regular	Homeopathic	Eclectic	Physio-Med. and Nondescript.	Total
1880	9,776	1,220	830		11,826
1890	13 521	1,164	719		15,404
1900	22,710	1,909	552		25,171
1901	23 846	1,683	604	224	26,417
1902	24 878	1,617	765	241	27,501
1903	24 930	1,498	848	339	27,615
1904	23,662	1,105	1,014	357	26,138

Number of Graduates —The total number of graduates for the year ending June 30, 1904, was 5,747, an increase of 49 over the preceding year The increase in 1903 over 1902 was 699, so that the increase during the present year was much less than that of the year previous Of course, there are 9 more colleges this year than there were last year, but 3 of the 9 were not in session, and the others, with the exception of 1, taught only a portion of the medical course Although the graduates have increased slightly, the matriculants have decreased considerably, and we must assume that the decrease has occurred largely in the freshmen classes, partly because of the increase in entrance requirements, partly because of the increase in fees and general expense of the medical course, and, perhaps because of the prosperity in the business world in general, which usually lowers the attendance in the professional schools In some colleges there was a decided falling off in the freshmen class, while in others there was a very slight increase The falling off was noticeable, particularly, in those schools that raised their entrance requirements The decrease in the number of graduates in the homeopathic schools—49—represents the lowest number of graduates since 1902 The eclectic schools show a decrease of 3 in the number of graduates below last year, and the other school a decrease of 1 In the regular schools, on the other hand, there has been an increase of 102 over 1903

Table of Medical College Graduates

Year	Regular	Homeopathic	Eclectic	Physio-Med. and Nondescript	Total
1880	2 673	380	188		3 241
1890	3 853	380	221		4 454
1900	4 715	413	86		5 214
1901	4 879	387	148	30	5,444
1902	4 498	336	138	27	4 999
1903	5 088	420	149	41	5 698
1904	5,190	371	146	40	5,747

Number of Colleges —Our report last year showed that there were at that time 157 medical colleges, 3 of which did not grant the degree of M D, but taught only the first two years of the medical curriculum Since then 1 college has passed out of existence, and 10 new ones have been formed, making a total of 166 colleges at the present time Of these 133 are regular, 19 homeopathic, 10 eclectic, 3 physiomedical, and 1 institution which teaches all the "pathies" and "isms," including osteopathy Of the regular colleges, 2 are not yet active and 7 do not grant any degree Of the latter number, 6 teach only the first two years of the medical course, and 1 only the first year Two of the regular colleges are located in our island possessions, one is the Medical Department of the University of Porto Rico at San Juan, and the other the Medical Department of the San Tomaso University of Manila, P I

Three colleges are exclusively for women, 60 for men, 103 are co-educational, 4 hold only night sessions, and 2 both day and night sessions There are 7 schools to which only colored people are admitted Four schools operate under the continuous course system, the year being divided into quarters, the student being allowed to attend only a specified number of quarters or semesters in each calendar year Sixty-six regular schools, 4 homeopathic and 1 eclectic college have a university connection or affiliation The baccalaureate and medical degrees are granted at the end of six years' study by 6 colleges, and at the end of seven years by 1 college

Seventy regular colleges are members of the Association of American Medical Colleges, 12 belong to the Southern Medical College Association 18 of the homeopathic schools are recognized as in good standing by the American Institute of Homeopathy, and 8 of the eclectic colleges are members of the National Confederation of Eclectic Medical Colleges Many of the colleges not in these associations abide by their entrance requirements

A study of the following comparative table of medical colleges is of interest The regular schools have increased in number since 1903, while the other medical colleges number as many as last year It must be remembered, however, that last year only 3 schools gave instruction in the first two years' work of the medical curriculum, whereas this year 7 schools were engaged in doing this preparatory work Each of these preparatory schools are integral parts of recognized universities, and this work, therefore is accepted as a full credit by other medical colleges By subtracting these 7 colleges, and also the 2 schools in Porto Rico and Manila, from the number of regular medical schools, it gives us an actual increase of only 2 colleges which grant the degree of M D, or a total of 156

COMPARATIVE TABLE OF MEDICAL COLLEGES

Year	Regular	Homeopathic.	Eclectic.	Physio-Med and Nondescript.	Total
1880	72	12	6		90
1890	93	14	9		116
1900	121	22	8		151
1901	124	21	10	4	159
1902	121	20	10	4	155
1903	121	19	10	4	154
1904	133	19	10	4	166

Length of Terms—A study of the length of terms in months, of the various medical colleges, discloses some very interesting facts Of the 163 schools from which we were able to obtain the necessary information, 40 3 per cent have a course of at least eight months' duration. Only 16 3 per cent have a course of less than seven months' duration The figures are as follows

TABLE OF COLLEGE TERMS

Term	Schools.	Per cent,
6 months	27	16.3
7 months	44	27 0
7½ months	22	13 5
8 months	34	20 8
8½ months	13	7 9
9 months	19	11 6
*10 months	4	2.4

*Night schools

Nearly all the shorter term schools are located in the South, where medical educators feel that the conditions are such as to prohibit a longer term Most of the nonsectarian schools have seven months' terms A very small percentage of the regular colleges have less than a seven months' term Many of the colleges which last year had seven months' terms have adopted the eight and nine months' terms for the coming year It is probable that another year will see the passing of the six months' school Of course, the term "months" is elastic, inasmuch as seven months means anywhere from twenty-six to twenty-eight weeks, eight months thirty to thirty-two weeks, and nine months, thirty-three to thirty-six weeks It would be far better to regulate the length of each annual course by specifying a definite number of teaching days or number of hours spent in college

Women in Medicine—It is of interest that in spite of the apparent passing away of colleges for women the number of women medical students and graduates has been increasing steadily During the past year only 2 of the 3 colleges for women were in session, but 97 colleges are co-educational, which may account for the increase in women students During the past year 1,129 women were engaged in the study of medicine—4 3 per cent of the total number of medical students and 244 graduated—4 per cent. of the total number of graduates Of the total number of matriculants only 183 were in attendance at the 2 woman's colleges, and 16 graduated from them

---

THE COUNCIL ON MEDICAL EDUCATION

With the appointment of the Council on Medical Education[1] at the Atlantic City session, the American Medical Association again voices its interest in the subject of medical education, and commits itself to an active participation in the efforts which are being made to elevate the standards of medical education in this country It is interesting that this step should have been taken at a meeting held within a few days of the death of the founder of the Association, whose dominant idea in proposing the organization of the profession, over fifty years ago, was the improvement of medical education The Council is to consist of five members, appointed by the President of the Association, and its functions are defined as follows

First, "to make an annual report to the House of Delegates on existing conditions of medical education in the United States"

Second, "to make suggestions as to means and methods by which the American Medical Association may best influence, favorably, medical education"

Third, "to act as the agent of the American Medical Association, under instructions from the House of Delegates, in its efforts to elevate medical education"

The plan to be pursued by the Council was left indefinite, and it will doubtless be its first business to determine what lines of work it will undertake and what its relations shall be to the several other organizations having a similar purpose Notwithstanding the gratifying advance which has been made in medical education in this country in recent years, as was well stated by the resolutions creating the Council, "the existing standards of medical education are not satisfactory as compared with those of other great powers" The conditions are ripe for a vigorous, concerted movement by all who are interested in the elevation of the medical profession in the United States In this movement the Association, with its enormous and increasing membership and its thorough organization, may be a factor of great importance It must proceed, however, with due regard to existing conditions, and will do best to co-ordinate its activities with those of existing organizations seeking the same end Some conditions peculiar to this country are mentioned in the resolutions to which we have referred, which state that "our form of government makes it impossible, or at least improbable, to obtain governmental control of medical education" The numerous medical colleges which have to do with the education of the student and the several examining and licensing bodies which guard the portals of the profession, are creatures of the several states, and beyond the reach of national control We can not have in this country, therefore, a body like the British Medical Council, which has direct official control of the several medical schools and of their students In its relations to the American Medical Association, and so to the general profession, the new Council is analogous to the Committee on Education of the British Medical Association, appointed in 1898

Another matter of importance is the existence of several national associations exclusively devoted to one or another phase of medical education, among them the Association of American Medical Colleges, the Southern Medical College Association, the National Confederation of Examining and Licensing Bodies, and the American Confederation of Reciprocating Examining and Licensing Medical Boards While the efforts of these associations have not always been as vigorous and effective as might have been desired, nevertheless each of them has special purposes in view, and is especially well adapted to the accomplishment of these purposes At the same time, they have some lines of effort in common, and much of the ineffectiveness of their previous activities has been due to the unnecessary and wasteful duplication of effort and the lack of co-ordination and co-operation The idea we have in mind may be illustrated by reference to some of the special acts by which the standards of medical education must be elevated

There is a general agreement that the preliminary education for admission to our medical schools falls far short of that which the conditions of the time require What should these standards be? Should the fitness of each student be determined by examination (and if so, by whom), or by the presentation of credits from certain recognized preparatory schools? If credits are to be accepted, who shall determine what institutions of general learning are to be recognized for this purpose?

The curricula of our numerous medical schools differ very greatly in the relative amount of time assigned to the several medical branches, and also as to the methods by which they are taught The degree of this absurd and illogical diversity has been well set forth by Dr George W Webster's recent paper, to which we refer elsewhere Something must be done to secure some degree of uniformity

The numerous and rapid changes which have been made in the curricula of our medical schools in recent years have resulted in a sad lack of mutual understand ing on the part of the medical schools, and it is becoming very difficult, in many cases, for the officials of an institution to pass intelligently on the credits of a student from another school seeking admission to advanced standing. This same lack of understanding and knowledge together with an utter absence of any uniform system in the issuing of credits, has made it possible for dishonest students to impose on the officials of a school by the presentation of altered or forged credentials, a very serious abuse greatly in need of correction.

---

[1] See Frontispiece

All of these matters belong properly to an organization of those engaged in the actual work of medical education, such as the Association of American Medical Colleges, though it might easily happen that the efforts of this association to advance along these lines would be more vigorous and successful with the prompting and co-operation of a body like the Council on Medical Education.

One of the most obvious needs of the time is some plan by which the numerous medical colleges may be compelled to live up to the standards which they set forth in their announcements. It is difficult to see how this end can be attained without a system of efficient and rigid inspection by an authorized and authoritative official. It would seem that such inspection could best be accomplished by an appointee of the Confederation of Examining and Licensing Boards. First, because the members of this confederation have actual need of the exact information which would be gathered by such an inspector, and secondly, because the examination by such an official, whose unfavorable report of an institution might result in the refusal to recognize its diplomas by most of the state examining boards, would be almost compulsory in its effect. Two other items naturally come within the province of this confederation. Now that a license to practice can be obtained in most of the states only by passing an examination conducted by the state board, the character of these examinations and the method of their conduct has come to be a matter of great importance, and it may be safely asserted that the present conditions are far from satisfactory. It is only necessary to allude here to the enormous importance of reciprocity in licensure between the several states.

Another important matter which might properly come within the province of the Council on Medical Education, is the suggestion of some plan by which the large and increasing amount of clinical material in the many hospitals springing into existence in the smaller cities can be utilized for the purposes of practical medical education. There is enough material of this sort to almost provide an interneship of one year for every medical graduate. It is only necessary, for the accomplishment of this desirable end, that the several medical faculties should be brought in touch with those in control of these hospitals that they may co-operate with each other. There are many other avenues of effort through which the standards of medical education can be elevated, but along most of these one or more existing organizations are already directing their efforts. What is especially needed at the present time is some means by which these various organizations may be made to co-operate effectively. Such an end could be best secured by a joint conference of authorized representatives of these organizations held under the auspices of the new Council on Medical Education. The Association might, of course, endeavor to enforce certain standards of preliminary and professional training by exacting compliance with such standards as a prerequisite for membership in the Association and its constituent societies. With the rapidly changing standards of the last few years, it would be difficult to formulate a list which would be at the same time just and effective. It is questionable, too, whether such an effort would not seriously interfere with that supreme purpose of the Association at the present time, to gather within its membership every reputable and right-minded physician. For the present, at least, we believe that the Association through the new Council will perform the largest service to medical education by the exercise of its moral force and by utilizing through co-operation the forces of the existing organizations to which we have referred.

THE EDUCATION OF THE INTERNE

It is generally conceded by the medical world that the education of the young physician is not completed when he leaves the medical school. Just what proportion of students in the United States take a year or more of hospital work after graduation is impossible to say. The Mosely Commission stated that, according to its information, 50 per cent. of all students took such a course. In our opinion this percentage is too high, but whatever the actual numbers, it is certain that most of us consider such hospital experience indispensable and that ambitious students strive for it. The reason that the number of graduate students entering the hospitals is not larger is lack of opportunity—not lack of applicants. From one to two years of what might be called practical apprenticeship is the privilege sought by the earnest student. To gain this privilege he often undergoes special training for a competitive examination, he delays for the period of his interneship his start in the world and his establishment in his profession.

The courses in the medical schools are subject to constant revision and improvement, and we are gradually rejecting the old method of didactic lectures to crowds of students and are substituting careful personal instruction to small groups. Indeed, the last decade has seen an almost revolutionary change in the methods of the schools. The interneship is the coping stone of the structure, and it is worth while to ask whether the methods of the hospital have kept pace with those of the school.

In old times the student entered the medical school and went to lectures as he pleased He was there to pick up knowledge as best he could The professor had no personal responsibility toward him It may be asked fairly whether this haphazard system does not still survive in many of our largest hospitals Does the hospital service, for which the interne sacrifices so much, count for all it should in equipping him for his profession?

Let us recall what occurs when the young graduate at last gains entrance as interne to the wards of one of our largest hospitals In the first place, he finds himself overwhelmed by the number of patients committed to his care To get through the routine work of the day usually taxes his powers to the utmost, and leaves him neither time nor energy for detailed work on the unusual and instructive cases Thus he is in great danger of forming at the outset the habit of handling his cases superficially—a habit which ruins him as a diagnostician Yet it is here in the hospital that he should acquire, under careful guidance, the methods to be followed throughout his professional life Many of us can recall with shame and amusement the helter-skelter "rounds," the hasty taking of histories, the farce of physical examination in cases which did not commend themselves to our youthful intelligence as interesting or unusual We have since found out, to our sorrow that it is these same unimportant cases which are most likely to prove stumbling-blocks to the superficial diagnostician

In contrast to the hasty methods of such hospitals there is much to be said for the leisurely learning which some of us enjoyed as we accompanied an honored Nestor on his daily rounds in a large family practice The number of cases seen was insignificant compared with those handled by the interne, but the sum of accurate observations at the end of a day was probably much greater Dr Toulouse, superintendent of one of the French public hospitals for the insane, speaks as follows of the interne service of such hospitals in words which apply only too well to the hospitals we are discussing

> Those internes who really wish to learn are deterred by the obstacles which they encounter at the outset The services are overcrowded, the daily round is so hurried that the inexperienced newcomer is overwhelmed by a crowd of details Before this accumulation of subjects which call for careful study the interne gives up the struggle for a scientific system of work "There are too many," he says, in despair, and it can not be too often repeated that there are, indeed, far too many

It would be unfortunate enough if this were the only result of allowing the interne to be thus overwhelmed by his material, but there is still another consequence which is even more detrimental to the scientific attitude of mind We mean the undue self-confidence which the interne is likely to exhibit when he rises above his first sense of helplessness It is fair to say, however that this overconfidence, this eagerness for independent experiment, is not the fault of the interne alone In the last analysis the failure of the hospital to give the proper training to its internes lies at the door of its attending men In the first place, the staff of some great public hospitals is encumbered with men who are incapable of teaching internes, and who have obtained their positions through political influence in order to gain prestige There are other men, able practitioners, but occupied by their private practice, who are content to allow their names to adorn the roster of the staff without personally appearing in the wards This leaves the legitimate work of the attending men to be performed by a totally inadequate number of physicians and necessarily frees the interne from proper supervision

We know that there are those who will take issue with us on this point We know the arguments usually urged that this absence of supervision gives a man self-reliance and ingenuity, that many of our most brilliant surgeons are the product of such training, or rather of such lack of training, but we are firm in our belief that careful supervision and instruction are invaluable, and that the brilliant surgeon and diagnostician has emerged in spite of no training rather than because of it

Why should we expect to reverse all educational laws at the entrance of the hospital? When the graduate in electrical or mechanical engineering leaves the technical school, it is insisted by the great railways and factories into whose employ he enters that he go through a progressive apprenticeship under skilled foremen He is not allowed to experiment with costly machinery on his text-book knowledge, much less with human life Would it not be better, for instance, that an interne should be taught to perform version under a skilled obstetrician, rather than that he should arrive at the proper method after a series of more or less disastrous independent experiments? Why do our students go to the German hospitals It is not so much because of insufficiency of material at home, it is rather that they are certain of receiving in the wards the personal instruction of the best men in Germany

Of course, what we have said does not apply to all American hospitals There are those whose service is not surpassed by any in the world On the other hand there is a true story of an interne who was seen in one of our large hospitals, and who, when asked how he was getting on, blithely replied "O splendidly, I like it so much better than ——— (mentioning an admirable instance of a carefully conducted hospital) About all you can do there is to follow the doctors around and watch what they do, but here the attending men are just figure-heads and never interfere with us"

What certain great free hospitals in this country need is a reorganization of the medical service which shall secure an adequate number of internes, and attending men who shall not be "figure-heads"

PRACTICAL EXAMINATIONS FOR LICENSURE

More than a quarter of a century has elapsed since the enactment in Illinois of the first effective medical-practice act in the United States The movement for the effective control of the admission to the practice of medicine, thus inaugurated, gaining momentum with the passing years, has advanced with especial rapidity in the last decade, until, at the present time, there are few states or territories in which the right to practice can be secured except the applicant submit himself to some sort of a test of his ability The most significant feature of this recent progress is the requirement of an examination conducted by the licensing board, in addition to the presentation of a diploma from a recognized medical school The licensing body is thus entirely divorced from the teaching body, and as these examinations are the sole avenue of entrance to medical practice, their character and conduct become a matter of supreme importance

Are these examinations, as now conducted, of such character as properly and adequately to test the fitness of the applicant to practice his profession Are they in line with the modern methods of medical education? During this quarter of a century the modes of instruction in our numerous medical schools have undergone a radical change The didactic lecture, and the lecture illustrated by the presentation of a patient in the arena or the performance of an operation (an exercise usually misnamed a clinic), have been supplemented, and to a notable extent, supplanted by laboratory and other practical methods It has come to be universally recognized that no person can become proficient in the study of disease and the treatment of the sick, at second hand—*solely* by the reading of books, listening to lectures, or the recitation of lessons committed to memory, however useful these means of instruction may be in connection with those of a more practical character Such proficiency can only be obtained by the study at first hand of the things themselves, by the training of the powers of observation, and of manual dexterity by their actual exercise

A board of medical examiners is a body appointed by the state to protect its people against incompetent persons laying claim to the special knowledge and training which are requisite for the intelligent practice of medicine *A priori* its function is, therefore, to demand evidence of such ability by such tests as will adequately demonstrate it Such evidence a purely written examination can never afford Such written tests, moreover, as are now universally in vogue, are an anachronism as a means of the examination of students who have been trained in the laboratory, the dissecting room, the practical courses in operative surgery, and in the actual contact with patients in the dispensary and ward clinic They put a premium on the obsolete methods of memorizing of text-books—of "cramming," in a word, which are the *bête noire* of all modern educators

Radical changes need to be made in these examinations in the immediate future While written papers as the most ready and convenient means of testing the applicant's knowledge, should continue to be required they ought to be supplemented by as many practical tests as possible Almost all of the medical branches lend themselves very readily to such practical examinations, which may be held without unreasonable expenditure of time, and with materials which can be obtained without serious difficulty In gross anatomy the applicants may be required to identify and describe cross-sections and dissected parts and to indicate, on the living subject, the important landmarks and the outlines of underlying structures, in histology, neurology and embryology, to identify and describe mounted specimens under the microscope, in bacteriology, to identify micro-organisms in culture and in cover-slip preparations, in pathology, to identify and make diagnoses from gross and microscopic specimens In the clinical branches such methods are also available The examination in medicine should include identification and significance of mounted cover-slips of blood, urinary sediments, sputum, feces, and other body products, he should demonstrate his facility in the methods of physical exploration on the living subject, for which purpose healthy individuals would suffice quite as well as those who are sick In surgery, operations on the cadaver, the application of bandages and other surgical dressings, and the preparation of himself, and a cadaver, serving as a patient, for an aseptic operation, might easily be required In obstetrics the manikin, with suitably preserved specimens of the fetus and the female pelvis, furnish means of testing his knowledge of obstetric procedures and his facility in their performance

The materials necessary for such examinations would gladly be furnished to the examining boards by the medical schools, laboratories and hospitals, at a minimum cost and in many cases without cost To the statement sometimes made that such examinations are not feasible, it is sufficient to reply that they have been in vogue in Great Britain and the nations of Europe for many years

---

MEDICAL STANDARDS AND THE PUBLIC SERVICES

The question of a standard of medical education which, in other nations, is simplified by the intervention of the national authority, either directly or indirectly, is in the United States rendered difficult of solution by the absence of such central authority Yet it is a fact that the National Government is interested in this matter, in that it has in the permanent personnel of at least four of the great executive departments a large number of physicians In three of them—the Department of War, the Navy and the Treasury which latter embraces the Public Health and Marine-Hospital Service—a high, and as near as practicable a fixed standard has been made a prerequisite to admission to the permanent medical service

In any serious movement looking to a national standard, the public medical services should be taken into consideration and their uplifting influence made of use and correlated to the requirements of such a standard. Examinations for admission to the Medical Department of the Army became habitual in 1832, and a knowledge of Latin and of physics was first required in 1849 In the Navy the first medical examining board was organized in 1825 A literary degree is not demanded of candidates, although evidences of marked lack of general education constitute a cause for rejection Although in the three public services the examinations are conducted by boards which have no connection with each other and under regulations which differ as to minor details, yet the qualifications required of candidates are approximately the same in each As the candidates for admission to the public services are drawn from all the schools and all parts of the Union, they are presumably neither better nor worse than those who come before the state boards of examiners for license to practice The subjects covered by the examinations are also practically identical Therefore a fairly accurate comparison between the average standard of the state boards and that of the public services may be made by finding the percentage of rejections in each In twenty states, being all from which the figures could be obtained, it was found that during the last five years 75 per cent of the candidates examined have been successful and 25 per cent rejected A summary[1] of the results of the examinations of 5,027 candidates for license to practice held by the boards of thirty-seven states during the year 1903, showed that 14 per cent were rejected In the examination for the three public services, not including those rejected for physical defects, out of a total of 1,035 examined, 347, or 33 5 per cent, have been successful, and 688, or 66 5 per cent have been rejected

We find here a standard respectable alike because of the number of competitors, the importance of the positions competed for, the broad sphere of its operation, embracing all the states, and because it is applicable to all schools of good standing While evidently too high for adoption by state boards, it is valuable as a comparative standard for them and should be considered in devising plans of interstate reciprocity It is also worthy the attention of teaching bodies, especially as it has been found necessary for each of these services to maintain at the National Capital a post-graduate school of high grade for special instruction in subjects which are peculiar to their needs, or which are insufficiently taught in even the best medical schools The subject of hygiene, including etiology and preventive medicine, which, as shown by Dr Webster's tables,[2] receives an average of only forty-six hours in the entire course of 124 medical schools, is the only subject taught in one of these service schools, and may fairly be considered the *raison d'être* of all of them Whether in the crowded condition of the medical curriculum and the ever-widening sphere of medical science, it will be possible to give the general practitioner a more satisfactory knowledge of preventive medicine is doubtful If not, the time has come to recognize preventive medicine as a well-marked specialty, and one of supreme importance to communities, states and the two branches of the military service

THE TABLE OF STATISTICS OF COLLEGES

On pages 504 and 505 will be found a table giving the states containing medical colleges, the name of each college, the population of the city in which the college is located, the number of men and women registered as students during the session of 1903-04, and also the graduates (men and women) of 1904, the total number of teachers, and the number of weeks in the college year The suffixes, R, H, E, P M, stand for regular, homeopathic, eclectic and physiomedical Much of the information to be derived from this table has been set forth in the editorial on medical education in the United States, page 466

DISTRIBUTION OF MEDICAL STUDENTS

The table showing the "Distribution of Medical Graduates," on pages 514 to 517, has its accompaniment in the table on pages 506 to 509, showing the states from which the medical students of each college come New York, Pennsylvania and Illinois furnish the majority of the medical students in this country Next come Indiana, Tennessee, Texas, California and Massachusetts Some of the states, such as Arizona. Delaware, Idaho and Florida, furnish a very small quota Densely populated cities and states, in which the people follow mercantile pursuits, furnish the majority of physicians, whereas the mining and cattle states furnish comparatively few The local conditions and the occupation of inhabitants of cities and states certainly influence the inclinations and propensities of men and women to study medicine Of the 26 138 medical students registered during the session of 1903-04 only 361 are not included in this table, so that it is sufficiently accurate to permit of making deductions These 361 students were registered in six or eight colleges, most of which are small, and can be disregarded in summing up Two of these schools are of some size, and as the majority of their students come from Kentucky and Indiana, the totals of these two states would be increased considerably

THE UNIFORM MEDICAL CURRICULUM

The report[2] on the curricula of American medical colleges made by Dr George W Webster, Chicago to the National Confederation of State Medical Examining and Licensing Boards, at its meeting in Atlantic City, discloses some very interesting information with reference to the inequality in the number of hours devoted to the teaching of the various subjects of the medical curriculum To some studies of but little significance and importance, a great deal of time is devoted while to others of prime importance to the physician too little time is given. Apparently, in some schools the professor of hygiene or of anatomy, or of chemistry is a very strong man, and the entire faculty has been built up around him, in fact, it is a one-man school Again, it is possible that an additional number of hours are devoted to work in the chemical or other laboratory in order to occupy the student's time Certain it is that a disproportion exists in the number of hours devoted to the various subjects Dr Webster has obtained his information directly from the colleges, yet it is evident that in some cases a discrepancy has crept in because, for example, it is beyond the possibilities of human endurance to put in sixteen hours a day in the college, even if this included the time to be devoted to study Dr Webster has compiled a table showing the average number of hours devoted to each subject in the curricula by 125 medical schools Although these figures can not, perhaps, be accepted as forming an ideal standard, yet they serve the purpose of permitting of the construction of a standard curriculum which is to be adopted as a minimum for the degree of M D, as follows The course shall consist of four terms, in four separate calendar years, each term to consist of thirty weeks of work, exclusive of holidays, and of at least five hours of college work each day, and thirty hours in each week, or nine hundred hours per year of actual work The entire course of four years shall consist of not less than thirty-six hundred hours of required work Any elective work should be in addition to the above Clinical work should constitute at least one-fourth of the total number of hours in the four-year course The adoption of a standard uniform curriculum, says Dr Webster, will be in the interest of higher medical education It will give to each subject that relative importance which rightly belongs to it It will enable students to receive due credit for work done in any recognized school which adopts and conforms to this standard It will serve as a basis for reform in state board examinations, and will make possible the interchange of licensure—reciprocity The medical degree will have a reasonably uniform standard of value, and will mean something to its holder

---

[1] The details of this summary are on pages 514 to 517 of this issue Incidentally it is interesting to compare the percentage of rejections in the past five years (25 per cent) with those in 1903 (14 per cent) Did the raising of the standards of the state boards cause more failures a few years ago and have the colleges since reacted to the stimulus and given their students better preparation so as to thus reduce the percentage of failures?

[2] Report on the Curricula of American Medical Colleges George W Webster N Y Med Journal July 23 and 30, 1904

DISTRIBUTION OF MEDICAL GRADUATES

We have tabulated—on pages 514 to 517 of this issue of The Journal—the reports of the state examining boards for the calendar year 1903 We consider this table well worth the careful inspection of all who are interested in the advancement of medical instruction. It is so arranged that by reading from left to right the individual medical colleges of the United States and Canada which grant degrees may be studied or comparisons readily made It shows where the graduates of each college are locating, the number who passed (P) and failed (F) in each state, the total appearing in all states from which we have received reports, together with the totals of those who passed and failed, as well as the percentage of failures Graduates of foreign colleges (this does not include Canada) locating in the United States are likewise shown Reading from above downward, the figures are given by states, thus allowing an easy comparison as to the number locating in each, the colleges represented, and the totals of those who were passed and rejected and the percentage rejected It will be seen that 5,027 applicants were examined in thirty-seven states, of whom 14 2 per cent failed Some state boards are more severe than others It is also interesting to note that some state boards appear to be lenient toward their own colleges, the graduates of these failing in more instances before the examining boards of other states The colleges of the few states from which we were unable to get full reports would undoubtedly have a better showing in our table had such reports been received, possibly from the leniency hinted at above, but more certainly from the fact that a very large percentage of medical college graduates come from and locate in the state which is the home of the college All the states are not represented in the table Several still do not require examinations Of those requiring examinations, the large majority promptly sent us reports Others failed to respond even after repeated requests Some pleaded lack of clerical help but some of these failed to respond even after The Journal had offered to pay the expense of copying the records But the most astonishing reply received to our request was the refusal of the examining board of one state to send the itemized report of failures asked for, since they feared that the reports, if published might put some medical colleges in a bad light! The Journal wishes to express its thanks for the hearty co-operation that, as a rule, has been received from the various boards The requirement of examinations in some states is but comparatively recent, and methods of record keeping are still in the evolutionary stage, and will doubtless improve The Virginia State Board published in detail the grades in each separate subject in which each applicant was examined This is of great value to the colleges concerned, since they can see in what subjects their graduates are weak, and take steps to strengthen the instruction in the department concerned

Miscellany.

New Colleges, and Colleges Discontinued.—During the year the following colleges were incorporated College of Physicians and Surgeons, Los Angeles, Cal, to begin work Oct 1, 1904 Bell Medical College, Dallas, Tex, the first session began Oct 1, 1903, the first and second years of the medical course are being given by the University of Indiana, Bloomington, Fordham College, New York, Lombard College, Galesburg, Ill., West Virginia University, Morgantown, W Va, and the University of Mississippi, Oxford. The University of the State of Washington is considering the formation of a medical department The National University Medical Department of Washington, D C, has been discontinued. Last year we announced the institution of a medical department by the Southwestern Presbyterian University, Nashville, Tenn, but we have been informed that work in this department has *not* yet begun, and probably never will be

Affiliation of Toledo Medical College—The Toledo Medical College is contemplating an affiliation with the University of Toledo

Medical Department University of Missouri Lengthens Its Course—This school is now working under a full four-year graded course, which has been recognized by the Association of American Medical Colleges as being up to the standard

Canadian Students in United States—In the table indicating homes of students, page 606, those marked "foreign" include Canadians This will explain the number in the foreign column in certain colleges located near the border

States That Have No Medical School.—The following states and territories contain no medical college Arizona, Delaware, Florida, Hawaii, Idaho, Indian Territory, Montana, Nevada, New Jersey, New Mexico, North Dakota, Rhode Island, South Dakota, Utah and Wyoming

Affiliation Contemplated by the Sioux City College of Medicine—Plans are being discussed considering an affiliation of this school with Morningside College Each school is to retain its identity, but the courses are to be combined in such a way that a student can complete his literary and medical work in six years, as is being done by other medical schools having a university connection

Index to Articles on Medical Education—The following partial list of articles bearing on the subject of medical education during the past year is given here for the convenience of those who may wish to look up the subject further It does not lay claim to completeness

Medical College Responsibilities of Carl S N Hallberg Med Standard N Y, August 1903
Colleges and Their Clinics, John Hunter Canada Lancet, January 1904
Curriculum E A Schafer Brit Med Jour, Oct 10 1903
Education and Preliminary Requirements, Geo H Simmons, The Journal A M A, May 7
Education in London, London Letter, The Journal A M A April 2
Education in the U S Frank S Billings, Med Herald, St Joseph Mo July 1903
Education Relation of Academic to W H Wathen, Am Prac and News, Louisville Aug 1 1903
Education Some Aspects of, John H Musser, The Journal A M A June 11, 1904
Graduate What Is to Become of the John L Irwin, Jour Mich State Med Soc April 1904
Instruction a Plea for Greater Uniformity, N R Coleman, N Y Med Jour Aug 1 1903
Instruction in the United States, Semaine Medical Paris (No 44)
School Chemistry of the, J H Long, The Journal A M A, April 9
Schools, Requirements for Admission to, N S Davis, Jr, The Journal A M A Aug 15, 1903
Studies in Europe John Sutherland St Paul Med Jour October, 1903
Teaching New Era in George E Nitzsche, Dominion Med Monthly May 1904

Medical News.

CALIFORNIA

College and Hospital Under Way—The excavation for the new $175 000 Angelus Hospital and for the building for the College of Physicians and Surgeons of Los Angeles was commenced July 14 The college building is to be ready October 6

Students' Hospital Will Be Enlarged—The joint committee on health from the student body and the faculty of the University of California, has decided to build an addition to the present building, which will increase the capacity of the hospital to 40 patients and will also provide the necessary accommodations for nurses, store rooms, service rooms and the like

Examiners Lose Case—On July 22 Judge Fritz dismissed the charge of practicing medicine without a license, which the State Board of Medical Examiners had preferred against Dr E Schmoll, *San Francisco, holding that while the accused* might have violated the law technically he had not done so deliberately

Faculty Dines—In order to get the workers in the new College of Physicians and Surgeons, Los Angeles, into closer touch, a banquet was held, July 16, at which 25 members of the faculty were present, and remarks were made by the president, Dr Charles B Nichols, the dean, Dr Benjamin F Church, the secretary, Dr J H Schults, and the treasurer, Dr James H Seymour

COLORADO

Eye, Ear and Throat Men—The ninth annual meeting of the American Academy of Ophthalmology and Oto-Laryngology will be held in Denver, August 24 to 26, under the presidency of Dr Edward Jackson, Denver

Phipps Sanatorium Opened.—The Agnes Memorial Sanatorium at Montclair, founded by Laurence C Phipps, at an expense of more than a quarter of a million, and dedicated to the treatment of pulmonary tuberculosis in memory of his mother, Mrs Agnes Phipps, was formally dedicated with fitting ceremonies July 2

Receive Degrees—A class of 32 was graduated from the Denver and Gross College of Medicine Prof Victor C Alderson and Rev Charles S Olmsted made addresses, and Prof Herbert A Howe of the Denver University conferred the degrees In the evening the graduating class was given a banquet by the faculty, at which Dr Sherman G Bonney was toastmaster

Personal—Dr Patrick V Carlin, Denver, has been elected a member of the Board of Education for the City and County of Denver——Dr Arthur T Blachly, Delta, has been appointed resident physician at the Hayward (Wis) Indian reservation——Dr Carl Parsons has been made resident physician at the City and County Hospital, Denver——Dr J M. Jordan has been appointed assistant county physician of Denver County, vice Dr Seymour T Jarecki, deceased

DISTRICT OF COLUMBIA

New Naval Medical School Building—Ground has been broken for a hospital building in connection with the Museum of Hygiene and Naval Medical School, for which $125,000 was appropriated by congress The building will be on the pavilion plan, with a central administration building and east, west and south wards

Georgetown Graduates—The Fifty fifth annual commencement exercises of Georgetown University were held, June 7, when 32 men were graduated in medicine Dr George L Magruder presided, President Daugherty conferred the degrees, and Assistant Surgeon General George Tully Vaughan of the U S Public Health and Marine Hospital Service delivered the doctorate address

Personal.—Dr Charles W Richardson, Washington, has gone abroad——Dr Charles B Purvis, Washington, has resigned from the Board of Medical Examiners, and Dr Daniel S Lamb has been appointed to fill the vacancy——Dr Patrick A Lloyd has succeeded T G Jones as chief resident physician at the Casualty Hospital, Washington——Drs Ray D *Adams* and Mahlon Ashford have succeeded Drs Samuel L Owens and Abrahams, as resident physicians at Georgetown University Hospital

ILLINOIS

Lawn Fete for Hospital.—The lawn fête given by the St Francis Hospital *Association at Evanston* last week, netted $1,400 to the funds of the hospital

Langdon Released Under Bonds—Dr P K. Langdon, recently extradited by the English authorities, was brought back to Kankakee, July 14, by the sheriff, and on July 19 was released under a bond of $10,000, will be brought before the grand jury in October

Personal.—Dr John W Bowling has been chosen to succeed Dr John F Barton as local surgeon for the Louisville and Nashville and Baltimore and Ohio railroads at Shawneetown Dr Frank Gardner has returned from Europe and is visiting in Sublette——Dr Frank N Armstrong, Richmond, was seized with apoplexy while in McHenry, July 25

Chicago

To and From Europe—Dr Edmund J Doering, sailed for Italy August 9——Dr Edward T Alford has returned from Europe.

Patients Rob Physician—Dr Johann Harraes was held up in his office, July 26, robbed of $300 in cash and $500 in jewelry by two men who posed as patients

Augustana Hospital.—At the recent meeting of the directors of this hospital it was announced that $20,000 had been bequeathed to the institution by the late Thomas D Lowther

Personal.—Dr H Gideon Wells has been made dean of medical work in the University of Chicago, vice Dr E P Lyons, resigned to accept a position in Washington University, St Louis

Swedish Hospital Incorporated—Articles of incorporation were issued, July 20, for the Washington Park Hospital, to be built near Washington Park The institution has a capital stock of $50,000, and has at present accommodation for 30 patients in a building at Sixtieth Street and Vincennes Avenue

Deaths of the Week.—Acute intestinal diseases caused 120 of the 473 deaths for the week ended August 6, consumption, 58, violence, 44, heart diseases, 34, Bright's disease, 33 and pneumonia, 27 The annual death rate per 1,000 was 12 78, which compares very favorably with 14 29, the rate for the corresponding week of last year

July Mortality—The deaths for July were 1,958, 213 more than were reported in June, and 432 less than occurred in July, 1903 The death rate for the month was 11 95 per 1,000 The deaths under one year were 122 less, and those between 1 year and 5 years 106 less than in July, 1903 The health department attributes the low mortality to propitious weather and a remarkably good water supply Acute intestinal diseases heads the list of death causes, with 333, consumption comes next with 233, and then follow violence, with 184, Bright's disease with 144, heart diseases with 143 and pneumonia with 123

IOWA

Accidents.—Dr Thomas J Maxwell, Keokuk, was run over by an automobile, spraining and abrading his knee——Dr Leo Louis, Parkersburg sustained internal injuries and injuries to head by being thrown from his buggy July 24

Fee Bill Adopted.—At a mass meeting of Des Moines physicians, July 28, at which 35 were present, a fee bill was adopted, providing for minimum charges of $2 to $5 for day visits, $3 to $5 for night calls, $15 for obstetrics, and charges for subsequent calls, and $2 for life insurance examinations This fee bill is to be in effect after September 1

Medical School Improvements.—At a meeting of the trustees of the Sioux City College of Medicine, August 3, a number of improvements for the college building were decided on These include the rearrangement of the interior of the building, the provision of an additional lecture room, and the purchase of more microscopes and other equipment for the laboratories

Personal.—Dr Robert E Conniff, Sioux City, has been elected president of the State Board of Medical Examiners—Dr Henry Matthey, Davenport, has been elected president of the State Board of Health, and Dr Josiah F Kennedy, Des Moines, secretary and editor of the Iowa Health Bulletin——Dr Henry Albert, professor of bacteriology in the Iowa State University, Iowa City, has assumed his duties as head of the bacteriologic department of the state.——Dr R. E Robinson, Waverly, sailed for Europe July 16——Dr Benjamin F Campbell, after a year of post graduate work in Chicago, has resumed practice in Burlington

KENTUCKY

Addition to Faculty—Dr Carl Weidner, Louisville, has been given the chair of pathology and histology in Kentucky University Medical Department

Twice Acquitted—Dr Sarah A. Murphy, Louisville, who has twice been charged with murder by a criminal operation, was acquitted for the second time, July 14, the judge ruling that the prosecution had failed to establish a case

Wathen Suggests Merger—Dr William H. Wathen, Louisville, announces that he thinks that the tremendous competition from medical institutions in other cities necessitates the consolidation of the five medical colleges in Louisville into two great universities

Cars Must Be Sanitary—The State Board of Health has entered on a vigorous campaign against unsanitary cars, paying especial attention to plush car seats, both for day cars and sleeping cars It threatens to indict all railway companies whose lines enter the state unless they provide sanitary cars, sanitary bed clothing in sleeping cars, and adequate ventilation

Personal.—Dr Miles C Dunn, Henderson, has been made chairman, Dr Robert H Moss, Niagara, temporary secretary, and Dr Silas Griffin, Henderson, health officer, of the newly organized Henderson County Board of Health——Dr James W Stephens, Hopkinsville, second assistant physician at the Western Kentucky Hospital for the Insane, has been made first assistant physician at the Central Kentucky Hospital for the Insane, Lakeland.——Dr Malcolm H. Yeaman has succeeded Dr Josiah G Furnish as superintendent of the Central Kentucky Hospital for the Insane, Lakeland.

MARYLAND

Many Autopsies Unnecessary—The Baltimore County Commissioner declined to pay bills for postmortem examinations The president expressed the opinion that many of them were unnecessary

Typhoid Epidemic.—There are 80 cases of typhoid fever at Mount Savage, Allegany County, the result of a contaminated spring, which has been closed by the health officer The disease is confined, with two exceptions, to men and boys One death has occurred so far The three physicians are kept busy night and day, and nurses have been sent from Cumberland.

Personal.—Dr Thomas C Baldwin, Gemmills, has resigned as health officer of the Seventh District, and has moved to Baltimore. The vacancy has been filled by the appointment of Dr Eugene W Hyde.——Dr John E Bolte, Harrisonville, was stricken with hemiplegia, August 4——Dr Charles W Goldsborough of Walkersville had his arm severely lacerated by two dogs, while visiting a patient, August 4

Baltimore

Baltimore Medical College has new laboratories of operative surgery and clinical pathology and a new museum

Purification of Water—The water engineer is purifying the city drinking water with copper sulphate with apparent success

Johns Hopkins Hospital.—The new surgical building (heretofore described in THE JOURNAL) will be ready for occupancy at the opening of the next session October 1

The Health Status.—The health report for July shows a considerable decrease in infectious diseases as compared with the same month in 1903, namely from 446 to 284 The general mortality is about the same.——During July at the public baths there were 61,232 visitors, of whom 8,406 were females, the largest number on record.

Modified Milk May Be Bought—The Thomas Wilson Sanitarium is operating five milk dispensaries in Baltimore, where for ten cents a day three pints of properly modified milk can be obtained for feeding infants Each dispensary has a physician and nurse, and any practitioner can order a supply of milk for the poor as long as needed.

University of Maryland.—A department of pharmacy has been created. A new dental building and new laboratories of physiology and pathology have been constructed A fund has been set apart by the trustees for research work Lectures on the history of medicine will be delivered weekly, commencing October 8 There is a fine medical library and collection of current journals.

Maryland Medical College.—Dr J B Schwatka has been elected dean, vice Dr J William Funck. Drs Charles E. Simon and Pearce Kintzing have been added to the faculty The former will give a practical laboratory course in clinical diagnosis to all members of the graduating class, the latter a course on physical diagnosis and clinical medicine The plans have been formulated and the money raised for the new Franklin Square Hospital, but the work of building will not be begun until after the next session

The Smallpox Crusade—The recent crusade against smallpox was highly satisfactory In all 72 850 persons were vaccinated, of whom 37,750 were treated by the 25 special vaccine physicians, 5,100 by the health wardens, and 30,000 by private physicians The total cost to the city was $6,750, $3,750 of which paid for special salaries, and the remainder for vaccine points Factory and mill owners now recognize the necessity of the measure and demand vaccination certificates from their employes The effect of the crusade is shown in the fact that in May 6 cases of smallpox were reported, in June 5 cases, and in July only one case.

Personal—Dr J B Schwatka sailed for Europe August 4 He was given a reception by his friends the day before he sailed ——Dr William H Welch left here, August 8, for San Francisco, where he is to deliver the Lane lectures on infection and immunity ——Dr William Osler is chairman of the Department of Medicine of the International Congress of Arts and Science, to be held in St Louis, September 19 to 25 Among the speakers from Baltimore will be Drs William S Thayer and Howard A Kelly ——Dr Isham R Page is at Northport, Maine ——Drs J William Funck and Seth S Ullrich are spending the month at Ocean City ——Dr Henry M Hurd will spend September in the Adirondacks ——Dr H Boyd Wylie is at Mountain Lake Park ——Drs John N Mackenzie and William T Howard are at Narragansett Pier ——Dr S Gibbons Smart of Roland Park has removed on account of his health to Bedford City, Va ——Dr M Gibson Porter, Lonaconing, has taken charge of his practice ——Dr Charles C Bombaugh is at Newport

MASSACHUSETTS

Domestic Science for Nurses—The Children's Hospital, Boston, has added to its curriculum for nurses a four months' course in Simmons College, the new training school in domestic science

Milk and Noise—Brookline has not only followed Boston in making a careful bacterial examination of the milk supply of the town, but in requesting the dealers to use more caution about early morning noises, much of which has been shown to be unnecessary

Sudden Rise in Mortality—After a series of weeks of most unusually low death rate, the Board of Health of Boston reports for the week ended August 6, 250 deaths, or an annual rate of 21 15 per 1 000 The great increase was in young children, 21 deaths during the week being ascribed to "cholera infantum" It is fair to presume that physicians use this term to cover cases of ileocolitis, for not a case of true cholera infantum has been received at the Boston Floating Hospital this summer, and over 500 patients have been treated there during the past four weeks

Summer Statistics—For the ten weeks ended August 6 there were reported in Boston 1,824 deaths, an average annual death rate of 15 57 per 1,000 There were 465 cases of diphtheria, with 31 deaths, 101 cases of scarlet fever, with 3 deaths, 119 cases of typhoid fever, with 19 deaths, 548 cases of measles, with 15 deaths, 401 cases of tuberculosis and 225 deaths, 140 deaths from pneumonia, 3 from whooping cough, 179 from heart disease, 28 from bronchitis, and 30 from marasmus, 410 died under one year old and 575 under five years In one week there was no death from diphtheria reported, the first time since 1901 In one week the death rate was only 11 58 per 1,000, and in another 12 06

MISSOURI

Will Elevate Standard—The following requirement was approved by the State Board of Health, and became operative July 5

> Every applicant for license to practice medicine in the state of Missouri shall present documentary evidence of having a university or college degree or high school diploma In lieu thereof, said applicant must pass a satisfactory examination before the state superintendent of public instruction on all branches embraced in a four years high school course
>
> This is an absolute requirement and no applicant will be allowed to enter the examination without having complied with this order

Licenses Revoked.—The State Board of Health, on July 6, revoked the license to practice medicine of Dr Samuel F March, secretary of the Kansas City Eclectic Medical University, who was charged with issuing irregular affidavits to students who graduated from the college last spring He was summoned before the board and admitted that the affidavits were irregular The board also revoked the license of J F Duvall, charged with obtaining a license from the board on one of the irregular affidavits of Dr March A license to A S McCleary was refused because his affidavit was also one of the irregular ones sworn to by Dr March The applications of five other members of the school's graduating class of last spring were considered Their records were found to be clean and the board voted to issue them licenses

NEW YORK

Convalescent Ward—A convalescent ward is being built at the Fresh Air Mission Hospital at Athol Springs

Personal.—Dr John Van Duyn has resigned from the Syracuse Board of Education ——Drs Nathan W Soblet and William S Rambo, Rochester, have been appointed local examiners in midwifery

Disinfection of School Books.—The Buffalo Department of Health is disinfecting 109,650 volumes of books of the public schools by the use of formaldehyd gas Since this work has been undertaken by the city there has been a decrease noted in contagious diseases, particularly scarlet fever and measles

Joint Meeting—After due consideration on the part of the officers of the Northern New York Medical Association and of the St Lawrence County Medical Society, it has been decided to hold the meeting of both bodies on October 18, at Ogdensburg, N Y, the association holding session during the afternoon and the society in the evening

High June Mortality—The total deaths for June were 10,997, or about 1,500 in excess of the average for that month in the last five years This is partially to be accounted for by the increase in deaths from violence in New York City, due to the *General Slocum* holocaust Deaths from cerebrospinal meningitis were the same as in April, and those from consumption exceeded the deaths from this cause in June, 1903, by 150

State Commission in Lunacy Appointments.—Dr Sidney D Wilgus, New York City, has been appointed by the State Commission in Lunacy as chief examiner, with a salary of $5,000 The last legislature passed a law creating a state board of alienists to act in concert with the United States examiners at the port of New York in the inspection and return to their own country of all emigrants suspected of insanity, epilepsy or imbecility As assistant examiners and members of the board the commission appointed Dr George D Campbell of New York City, and W E Sylvester of College Point, each with a salary of $3,000

New York City

Summer Home and Hospital for Poor Children—Miss Margaret L Chanler has transformed her house into a summer convalescent home and hospital for poor children, especially of Christ Church parish

Shrady Resigns—Dr George F Shrady, after nearly forty years of continuous service, has resigned the editorship of the *Medical Record*, Dr Thomas L Stedman, who has been associate editor for nearly twenty years, being appointed in his place The personnel of the editorial staff, it is said, remains as before Dr Shrady's resignation

Contagious Diseases—For the week ended July 30 there were reported to the sanitary bureau 341 cases of tuberculosis, with 170 deaths, 202 cases of diphtheria, with 24 deaths, 183 cases of measles, with 8 deaths, 88 cases of scarlet fever, with 8 deaths, 83 cases of typhoid fever, with 13 deaths, 11 cases of varicella, 1 case of smallpox, and 25 deaths from cerebrospinal meningitis

Rockefeller Institute Plans—The plans for the Rockefeller Institute have been filed and work will be begun soon It is estimated that the building alone will cost $325,000 Mr Rockefeller has already donated $1,200 000 In addition to the most perfectly equipped hospital in the world, there will be scientifically constructed accommodations for horses and other animals to be used for purposes of inoculation One of the first enterprises of the institute will be the endeavor to find and identify the germ of dysentery, and to ascertain means of preventing and curing the disease

NORTH CAROLINA

Wake Forest School of Medicine has commenced work on its new building, which is to cost $30,000 The cornerstone was laid at commencement time, and Dr J Allison Hodges, Richmond, delivered the address before the medical class

Donation for Negro Hospital—Dr William H Sprunt, Wilmington, has donated $10,000 to build an annex to the James Walker Memorial Hospital, to be used in erecting a dormitory for nurses, and a building for the exclusive care of negroes

Smallpox in the State—For the year ended May 1, 1904, 5,370 cases of smallpox were reported, 914 more than for the previous year, with 69 deaths In Guilford County there were but 101 cases, of which 94 were among the whites Robeson County reports 1,000 cases of which 300 were among the whites In Madison County there were 587 cases, all but 12 being among the whites The disease was of a bad type in Davidson County, where 25 deaths resulted.

Commencements—North Carolina Medical College, Charlotte, formerly the Davidson Medical School, at its first commencement exercises, graduated a class of 17 Dr J Howell Way, Waynesville, delivered the doctorate address, and Dr J T

Monroe, Davidson, presented the diplomas ——The Medical Department of the University of North Carolina, Raleigh, held its graduating exercises at Chapel Hill A class of four received diplomas, and Dr Louis J Picot, Littleton, delivered the address of the evening

State Society Election—The fifty first annual meeting of the Medical Society of the State of North Carolina was held at Raleigh, May 24 26 The following officers were elected President, Dr David T Tayloe, Washington, vice presidents, Drs Charles A Julian, Thomasville, John T Burrus, High Point, and Isaac W Faison, Charlotte, secretary, Dr J Howell Way, Waynesville, treasurer, Dr Granada T Sykes, Grissom, Dr Chase P Ambler, Asheville, orator, and Dr John H Tucker, Jr, Henderson, essayist The society is to meet at Greensboro next year

NORTH DAKOTA.

Cass County Physicians.—Dr John D Hennings, Fargo, has been appointed physician of Cass County, with the following assistants Drs Krekore H Mallarian, Fargo, A F Goffelee, Grandin, Evan Hyslin, Kindred, Samuel Mitchell, Mapleton, Kelsey, Erie, Hezekiah J Rowe, Castleton, Henry G Fish, Wheatland, William Scanlan, Page, and John W Campbell, Tower City

State Society Meets.—At the meeting of the North Dakota State Medical Society in Fargo, much time was taken up in the consideration of the new constitution and by laws to correspond with those of the American Medical Association Dr James A. Rankin, Jamestown, was elected president, Dr Paul Sorkness, Fargo, vice president, Dr Ernest C Wheeler, Fargo, secretary, and Dr William H. M Philip, Hope, treasurer

June Vital Statistics.—During June 288 births were reported to the State Board of Health and 118 deaths Fourteen cases of tuberculosis were reported, with 11 deaths, 7 cases of typhoid fever, with 2 deaths, 22 cases of diphtheria, with no deaths, 21 cases of scarlet fever with 1 death, 8 cases of measles, with 1 death, 0 cases of smallpox, with no deaths, 9 cases of other contagious diseases, with no deaths, making 15 deaths from contagious diseases

OHIO

Must Include Anatomy—The Ohio Medical University Columbus, will no longer allow credits on the degrees issued by colleges unless the prescribed courses shall include anatomy and other essential studies

Mayor's Veto Sustained—The last official communication of the late Mayor Jones of Toledo to the city council was a veto of an ordinance granting right of way to physicians and ambulances, on the ground that it established a special privileged class The veto was sustained by a vote of 9 to 7

Anti-Tuberculosis Dispensary—The trustees of Western Reserve University, Cleveland, have voted to take part in the conflict against tuberculosis by establishing a dispensary in connection with its medical department, whose function will be chiefly preventive It registers those infected with the disease, locates houses in which tuberculous people live, educates the people along fundamental hygienic lines, and its agents visit the homes of the sick, and give instruction in the care of those afflicted with the disease

Toledo University Department of Medicine—The Toledo University has established its medical department, Toledo Medical College The work under the new auspices will begin next month The following named men have been selected as faculty of the new department

Drs William A. Dickey dean Park L Myers, secretary Joseph T Woods, emeritus professor surgery and clinical surgery John North emeritus professor nose throat and lungs Hon D R Austin emeritus professor medical jurisprudence Drs William J Gillette professor gynecology abdominal surgery and clinical surgery William A Dickey professor principles and practice of medicine and clinical medicine Daniel E Haag professor therapeutics, microscopy and clinical medicine Park L. Myers professor chemistry toxicology and state medicine Willis W Grube professor clinical medicine and lecturer on anesthetics Oscar Hasencamp professor principles and practice of medicine and electro-therapeutics James Donnelly professor principles and practices of surgery and clinical surgery David F Bowman professor of obstetrics Elmer W Heltman professor ophthalmology and otology Lyman A Brewer professor surgical and clinical surgery Bernard Becker professor surgical pathology John S Pyle, professor physiology and embryology James A Duncan professor proctology Louis Miller professor nervous diseases Julius H Jacobson lecturer on physical diagnosis and clinical surgery at Lucas County Hospital George F Wells LL.B professor medical jurisprudence Drs Herbert E Smead professor of pediatrics Howard L. Green lecturer on minor surgery Charles Louy lecturer on osteology syndesmology and assistant demonstrator of anatomy Adolph J Girardot lecturer on materia medica William H Fisher lecturer on gynecology and clinical surgery Albert L. Sternfield professor histology pathology director of biologic laboratories and instructor in clinical microscopy Nelson H Young lecturer on mental diseases Edwin D Tucker lecturer on dermatology Louis M Dolloway lecturer on nose and throat Madison E Baldwin lecturer on genito-urinary diseases James T Lawless special lecturer clinical surgery, St. Vincent s Hospital, and L. A. Levison lecturer on anatomy

PENNSYLVANIA.

Typhoid Fever at Pittsburg—The bureau of health reports the prevalence of typhoid fever in Pittsburg and states that the number of cases bids fair to equal or surpass the record of last summer

Butler's Water Supply Improved.—Tests of the water supply of Butler have been made at varying intervals since the epidemic In all 25 tests have been made, and all thus far have been favorable The last two tests were conducted by Dr Francis C Phillips of the Western University of Pennsylvania, who reports that the specimens contained 15 and 21 bacteria per cubic centimeter and that the colon bacillus was not found.

Philadelphia.

To Enforce Vaccination.—The report of the 50 medical inspectors for last week shows that 6,674 visits were made, that 900 vaccinations were performed, and that 194 persons refused to submit The names and addresses of these individuals are registered in the department of health and rigid measures will be instituted to enforce vaccination

Health Report—The city's health continues exceptionally good The deaths reported for last week aggregated 428, a decrease of 6 from last week and an increase of 5 over the corresponding period of last year Smallpox has entirely disappeared, no cases having been reported since July 9 This is the longest period the city has been totally free from the disease for several years Typhoid fever, on the other hand, continues present throughout the city, though the disease is most prevalent in the district of Kensington The cases reported for the week numbered 84, an increase of 22 over last week There were 179 cases of contagious disease reported

Health of Pupils.—The report of the inspection of public schools for April, May and June shows that of 155,707 children examined, 6 936 were excluded because of disease. In 5,150 the eyes were affected. Of this number 1,807 were obliged to wear glasses, 317 schools were visited, comprising the combined grammar and primary, the grammar, primary, combined primary, consolidated, combined grammar, kindergarten, and special schools Among the principal causes mentioned for the exclusion of the pupils were Pediculosis, 3,854, ringworm, 434, defective vision, 421, eye affections, 420, tonsillitis, 349, impetigo, 407 The inspection is to continue monthly after the schools open next month, as the results show that the general health of the pupils is decidedly improved.

Hospital Work for July—At St Agnes Hospital 164 patients were treated in the wards, 593 new cases and 2,103 old cases were treated in the various dispensaries ——In St Joseph's Hospital 298 patients were treated in the wards and 2,507 patients in the different dispensaries ——In the Presbyterian Hospital 422 patients were treated in the wards, and 2 382 in the dispensary ——In the Medico Chirurgical Hospital 103 patients were treated in the wards, 1,313 in the surgical dispensary, and 1 325 in the eye department A total of 5 899 patients was treated during the month ——Three hundred and thirty five patients were admitted to the wards of the Pennsylvania Hospital, 2,193 were treated in the receiving wards, and 5,746 in the out patient department ——In the wards of the Episcopal Hospital 287 patients were admitted and 285 discharged, and in the different dispensaries 7,711 patients were treated

FOREIGN

French Donations to the Russian Red Cross—The ambassador of France to Russia has presented to the Russian Red Cross the sum of $23,000 raised by subscriptions through the lay press of Paris

Number of Medical Students in Germany and Switzerland.—The number of medical students enrolled in the universities of Germany for the current year is 6 049 In Switzerland there are more women than men studying medicine the total being 1 654, of whom 801 are women, mostly Russians

Record-Breaking Fees.—The community of Kallstadt, Germany has about 1 100 inhabitants, and has recently installed a medical school inspector with the annual salary of 25 marks, or about $6 25 He is to have about 155 school children to inspect four times a year He thus receives four cents for each child, or one penny for a single examination

Warning Against the Study of Medicine—The organized profession in Germany has issued a circular warning youth against the medical career It points out the over crowding of the profession in comparison to the population, and depicts the material depression prevailing in its ranks from the lack of restrictive legislation against quacks and of regulation of the sickness insurance societies

Ross and Weir Mitchell Elected to the Paris Academie de Medecine—The candidates for the two vacant places of corresponding members in the medical section of the French National Academy of Medicine were Ronald Ross of Liverpool, our own Weir Mitchell, Mosso of Turin, Ehlers of Copenhagen, Unna of Hamburg and Pick of Prague Ross and Weir Mitchell were elected by large majorities at the meeting on July 19

Konig's Retirement—Frank König of Berlin has just witnessed the completion of the model surgical clinic erected for him at the Charité, and now he retires, as he has passed the age of 72 His successor is already announced, A von Eiselsberg of Vienna, Billroth's favorite pupil He has already been connected with a German university, having been professor of surgery at Königsberg, 1895 to 1901, after having served a term at Utrecht

Loss to Science of a Living Students' Manikin—The death is announced of the Vienna woman, who supported her family by serving as a subject for the study of the upper air passages She had followed this means of livelihood for twenty years, and had cultivated her vocal organs so that she had voluntary control over them and could hold them still, even when they were being touched, thus affording incomparable opportunities for study of the respiratory organs She had also learned so that she could tell the investigator when his instrument was following a false route or any other mistake was being made She always carried a number of "foreign bodies" in a black bag, and would introduce one at a time into the upper air passages and allow the student to search for and extract them

Russian Tributes to their Japanese Opponents.—The *Russische med Rundschau* quotes a Russian physician, who has lived long in Japan, to the effect that the most astonishing cleanliness and system reign in all the Japanese Red Cross hospitals and dispensaries The beds are wide and remarkably neat A letter from a Russian physician at the seat of war (Wafangou), published in the last *St Petersburg med Wochft*, describes the battles of June 13 and 14 as "frightfully bitter" "Nothing was to be seen and heard but smoke, dust, noise, thunder and tumultuous din The Japanese came on with an altogether unexpected and all compelling energy Our troops behaved nobly, but no one could withstand the firing The tops of the hills were literally swept bare of foliage, and after the battle looked like ploughed fields"

New Technic of Sex Determination.—Ducceschi and Tallarico of Florence, Italy, recently described researches which signalize a new, rational and ingenious mode of studying the problems of the determination of the sex of the embryo Their communication was presented to a local scientific society and published in the *Archivio di Fisiologia* for July It is based on the recently established fact that after injection into an animal of the elements constituting an organ in an animal of a different species, the serum of the first animal acquires a destructive action for the organ in question They assumed, for instance, that injection into a gravid animal of substances known to have a specific, destructive action on the testicles, would entail the passage of these substances into the fetal organism, and have an inhibiting action on the development of the male sexual organs, while the female sexual organs would not be affected. Consequently, if the injection were made in the earliest stages of gestation, before the sex of the fetus was actually established it would prove the determining factor in deciding the sex of the embryo They have been experimenting with an orchi-toxic serum on gravid guinea pigs, and although their experiences are as yet very limited, they suggest a promising field for further research

Discovery of the Micro-Organism Causing Pulmonary Phthisis—Prof Otto von Schrön of Naples is one of the most venerated masters of pathologic anatomy of the Italian school He has recently announced that tuberculosis and phthisis of the lungs are two separate morbid entities, although very frequently they may occur together in the same individual The causal agents differ in each, by their structure, morphogenesis and biologic characteristics The accumulations of caseous material in the phthisic lung are not necrotic tissue as hitherto supposed, they are formed by a highly organized germ, which grows in threads and branches, an arborescent microbe, with distinct fructification, taking stains readily, in all the phases of its morphogenetic evolution It can be obtained in pure cultures by the drop method or in symbiosis with the bacillus of tuberculosis in cultures *in vitro* The phthiseogenic microbe substitutes the lung tissue, and does not cause necrosis like the toxins of the tubercle bacillus Each phthisic cavity presents three layers, the outer one formed by the evoluting forms of the microbe, while the inner layers are the dead and decaying forms, sometimes with and sometimes without the presence of tubercle bacilli It has a certain superficial resemblance to hyphomycetes, but differs in essential points The arborescent ramifications can be seen with a Zeiss oil immersion 1/18, but Schrön has devised a technic for investigation by which the ramifications can be seen with the naked eye We find life in the caseous material where we supposed there was nothing but death and decay He calls it the filiform microbe, as the thread formation is its most striking characteristic, possibly compelling its classification among the fungi It passes through a phase of thread and capsule formation, with a racemose and lichenoid growth, and finally into mucous metamorphosis, which is the stage in which it appears usually in the sputa It does not take the same stains as the tubercle bacillus, but stains readily with certain others The products of its secretions are prisms with a hexagonal base, polarizing light, while the products of the tubercle bacillus are non polarizing rhombi Both forms of crystals are generally found in the sputa of phthisic subjects

Correspondence.

Co-ordination Between Clinical and Didactic Work.

PHILADELPHIA, Aug 2, 1904

To the Editor—May I avail myself of the opportunity, which your Educational Number will give, of expressing some views on medical education arrived at after a number of years' service as a teacher of clinical medicine? The remarks I shall have to make relate to the practical branches only, the teaching of the purely scientific subjects is quite another matter I wish further to add that my remarks have reference to the senior year of study Physical diagnosis, clinical pathology and history taken properly belong to the pre-senior years

It would be impossible to draw up an ideal scheme for the teaching of medicine and surgery without taking into consideration available material, its distribution and other local conditions, the number of students, etc Whatever the conditions, there must be a co ordination of different methods of teaching and a suitable apportionment of the student's time When laboratory and clinical teaching were introduced into the curriculum of medical schools many were led to the conclusion that the didactic lecture was doomed to suppression, a conclusion which seems to me unwise and unwarranted by experience It may be freely granted that the amount of time devoted to such lectures in some schools is still excessive, but, on the other hand, it is too exalted appreciation of practical work that would supplant the lecture entirely The presence of the teacher, the *vox viva*, and the resulting impression made on the average student's mind give the didactic lecture an advantage over text book study that is real and appreciable Practical work must not be compared with the lecture for no amount of clinical material and no reasonable lengthening of the medical course would make it possible for the student to gain the desired acquaintance with disease in its many variations through practical work done in the medical school The comparison properly lies between didactic work and text book study, and here certain advantages are undoubtedly on the side of the lecture Reading must, of course, form a supplemental part of the student's training, and I am not disposed to deny that there may be a student now and then who could with advantage omit the lecture in favor of study, but such individuals are exceptional

The subdivisions in the practical teaching of medicine and surgery now commonly recognized are The clinical lecture clinical conference, ward class, work in the wards of the hospital and dispensary, and laboratory classes Each of these has a separate sort of usefulness and must be given a share of the total available time in accordance with local facilities. Nowhere, however, can the best results be achieved unless the advantages of these different methods of instruction are secured.

The ward class is valuable according to the way in which it is conducted. My experience with students at the University of Pennsylvania has been that they learned more of that which it is most important to learn, in ward classes than in clinics, clinical conferences or work in the wards. The ward classes are composed of not more than ten men, and each group is taken to the bedside by an instructor, who usually demonstrates but one case during the hour. The instructor reviews this case thoroughly, taking up the history, the symptoms and the physical examination systematically. The classes are small enough to allow each student to percuss, auscultate, etc. The important advantage of such a class is that it teaches *method*, and it is method more than a mere collection of facts that should be taught in practical courses. Compare such a class with the large "ward classes" of the English schools and the advantage of the former becomes obvious. The English ward class, as I have seen it conducted, is a class of from 20 to 30 men, who walk through the ward, stopping at one bed after another, to be shown some interesting feature in this or that case. The result of such a plan must be to teach superficiality and unmethodical work. In reality this is not a ward class at all, the same instruction could be given equally well as a large clinic.

An institution committed to the small ward class method must be prepared to supply a large number of instructors for the subdivision of the class in several fold as great as when the larger classes are given. At the same time the number of teaching hours given to each student will necessarily be less than could be given to larger groups, but the advantage of the method more than compensates for the reduction in hours, whatever appearances may seem to indicate.

The value of ward work depends on the system and to a large extent on the student. Our method is to assign the members of the fourth year class to duty in the wards, each student being placed in charge of certain beds. During one hour each day he is required to examine his patients, make blood counts, urine examinations, etc., under direction of the resident physician, the following hour one of the physicians or assistant physicians makes the "rounds" accompanied by all the students working in that ward. At each bed he questions the student in charge and discusses the case briefly with all. Valuable as this method is when combined with the ward class (or, better still, when preceded by the ward class), the ward visit taken by itself would be inadequate. It gives the student a certain responsibility and independence which brings out his best work under proper guidance, but unless the supervision is immediate and constant (which is almost impossible) it fails, unless provision is elsewhere made to teach the required method.

The clinical conference is properly compared with the larger ward classes alluded to before. Our method is to assign two students to a case in the ward and to discuss this case with a group of from 25 to 50 students before whom the two, specially selected to study the case, make their report a week after the assignment. A number of the students may be called to the bedside to confirm or correct assertions of those reporting the case, thus increasing the interest of the class and at the same time utilizing the material for the benefit of the greatest number possible. The advantage of the clinical conference is that it gives the student the greatest independence in case study with the subsequent advantage of criticism by his fellows and the instructor. It can not however, supplant the ward class or ward work.

The general clinic or clinical lecture has somewhat the same advantages as the didactic lecture in so far as the spoken words of an experienced teacher impress themselves on the student's mind more indelibly than the best text book descriptions, and the practical demonstration of the method of obtaining a history, of conducting a physical examination and of forming deductions is of incalculable advantage. It may be said that but few of the students in a large clinic are near enough to the operations or even the visible signs in medical cases. This is undoubtedly a defect of the general clinic, but its other advantages make it indispensable in a properly rounded medical course. As long as judgment based on experience and deduction are a necessity to medical diagnosis, the practical exposition of a master's method will be a useful part of teaching. Physical examination, the procedures of microscopic and chemical investigations and the systematic consideration of symptoms may be better taught in the ward class, laboratory, didactic lecture or library, but diagnosis in its broadest sense and refinements of treatment are best imparted in the clinic.

Work in the hospital dispensary or out patient department and laboratory classes are properly a part of the pre-senior year of study, as they are in most respects preparatory to the finished work of the last year and necessary to the student's proper utilization of the advantages of his final year of study.

Whatever proportion of time is properly allotted to each of the methods of practical teaching, it is always important that the peculiar advantages of the methods be recognized to the end that their individual merits may be realized. Clinics are sometimes conducted as didactic lectures, while ward classes or conferences are converted into clinics. Such changes detract from the system as a whole and defeat its proper purpose. Above all else, the most essential requisite to successful teaching is a well conceived system conscientiously carried out.

ALFRED STENGEL.

The Failure of the Laboratory Worker as a Practitioner

GALESBURG, ILL., Aug. 1, 1904.

To the Editor:—I was one of those who enjoyed the hospitality of the University of Pennsylvania during the dedication of its new medical laboratories at the close of the Atlantic City session. I was greatly impressed, as every one of the Association members must have been, with the evident completeness of the great building for the purposes for which it was designed. I was also interested in viewing the exhibit of the work which had been done in recent years by the students in the medical department, the exhibit from the course in surgical pathology being especially fine. From Philadelphia I went to one of the coast cities in the East, where a large number gather each year for medical instruction. There I learned personally of some of the methods of instructing medical students, both graduate and undergraduate.

It has been my privilege and pleasure within a few years to have associated with me some of the younger men who were the products of the present educational methods in medicine. I regret to say that what they brought to me, practically, was not an unalloyed advantage. In three instances they had been sent out from as many recognized schools. One graduate, indeed, was thrice the recipient of a gold medal for proficient and accurate work during his medical course. But in the small laboratory of a fairly successful practitioner, and away from the apron strings of their instructors, the accurate and therefore usable knowledge which these young men possessed was a minus quantity. To one who had been trained in a large eastern school at a time in the long ago, when twenty lessons comprised the course in histology, pathology and bacteriology, it was felt that these young men were needed. They came, and they all went the same road. For pathology they brought guesswork, for bacteriology, guesswork, for blood and urinary examinations, guesswork.

Now, some one in defense of these young men, may say that the above statements can not be literally true, if the young men were of average ability. But their average ability was and is unquestioned, and they were given every facility for scientific work. True it is that they possessed knowledge of these subjects, but it was rudimentary to the degree that it did not rise above the rule in any well regulated physician's office making no pretensions to special knowledge. With an experience such as this, educational methods in medicine had an added interest.

In the city last referred to I visited one school which, however, does not possess the degree giving power, but whose facilities for good clinical work are recognized everywhere In the four weeks that I was there I saw and heard some things that, partially, at least, explain why my assistants, when they came out of school, were not ready to practice medicine any more than were their forefathers To illustrate One young man who had been in practice six years came in to take a course on the blood and urine He had but two weeks to devote to these subjects, and knew nothing of them except what was gained from his college course six years before He commenced his work by studying the urine with the microscope, and continued this until two days before he was to leave the school In the remaining two days he was given instruction on the blood This consisted of the writing in a book by the instructor of the names of the various objects found in the blood plasma, also a demonstration as to the method of counting the red blood corpuscles This was the first day The second and last day of the course was devoted to counting the white blood corpuscles, and the exhibition of a number of slides showing the various forms of the malarial plasmodium

During the course the instructor was overheard to remark to this would be seeker after medical knowledge that he was very fortunate in taking special instruction on these subjects, because in the regular graduate schools it was impossible to devote the time necessary for their proper understanding This instructor must have known, because he holds a professor's chair in one of the eastern graduate schools

I know this to be an extreme illustration, but, unfortunately, when we attempt to grade up we find enough of incomplete medical instruction in all of the schools, both east and west, to account for the personal experiences related above And so I am going to venture the criticism, without knowing much about the subject—except from the standpoint of the user of the products of these methods—that too much that is impracticable for use by the busy practitioner working alone, is attempted in our schools

Many patients will prevent the unaided physician from even attempting an accurate diagnosis, hence medical men are drifting into specialism, because they instinctively feel that this will give them a better opportunity to see a larger number of cases of one class All things being equal, it will, but the result usually is that we then have a one sided practitioner, which is unfortunate both for medicine and the public After the specialist has learned his limitations he calls to his aid other specialists This has brought about the newest phase of the practice of medicine, known as "passing them around"

As a general proposition, the man in medicine, be he general practitioner or specialist, working alone, is seriously handicapped because time prevents his using the very methods that would mean so much for him in the betterment of human health The lone specialist, under these conditions, can not hold his place, and the general practice of medicine will likewise fail to progress in proper measure until some method can be adopted whereby the profession, in larger numbers, can really use the facts provided by the schools and laboratories Too many subjects are imperfectly taught, the profession crowded with more than it can carry in the way of undigested knowledge This can be said of all professions, and all teaching, but it ought not to be true of medicine The public has been taught of late that the science of medicine is traveling in seven league boots This is true in the greater measure only of that part which deals more particularly with the investigation and experimental side of medicine I repeat, unfortunately, the results attained by this class of workers can not find its highest place until it can be utilized by all The schools and laboratories are never going to get this knowledge into the hands of the profession while the present methods for its dissemination are depended on The supply is greater than the ability of the average man to use it

That a way to use it will be found finally I am convinced I am not so sure but that the way has already been pointed out The men who have formed (in the larger cities mainly) the more or less loose alliance whereby it is possible to follow the reprehensible practice of passing patients around, point the way These practitioners are usually a bunch of specialists who are agreeable to each other

The ideal state will be when these men are gathered together in one office and under a joint management A patient entering such an office would be thoroughly examined during his first consultation The results of such an examination, submitted to the general medicine man of the combination, or the surgeon, would insure in the beginning that consideration which is absolutely necessary for the patient's ultimate and best welfare Only by some such method as this can the advanced work of the colleges and laboratories be utilized

Indorsement in Lieu of Reciprocity Between State Licensing Boards

Camden, N J, July 5, 1904

To the Editor —I take pleasure in forwarding you resolutions on the New Jersey method of interstate exchange of medical licenses, which I introduced at the last meeting of the National Confederation of State Examining and Licensing Medical Boards, Atlantic City, June 6, 1904 After discussion the resolutions were ordered to lie on the table, to be printed by the secretary, distributed among the members and presented for consideration at the next meeting I would be obliged if you would print them in The Journal E L B Godfrey

Secretary of the State Board of Medical Examiners of New Jersey

THE PROPOSED RESOLUTIONS ON INTERSTATE INDORSEMENT VS INTERSTATE RECIPROCITY

Whereas, National legislation can not affect the question of state jurisdiction in medical practice without the surrender of definite state sovereignty and

Whereas State medical examination is the basis for state medical license or the indorsement of a license issued after an approved examination of another state, and each state is the judge of the qualifications of its medical licentiates and

Whereas It is manifestly unjust and a cause of open complaint by the profession to compel an experienced physician licensed after a state examination, to undergo a second examination (practically a re-examination in the same elementary branches) on removing from one state to another, when the requirements for medical license in the two states are substantially the same, or lower in the state from which indorsement is asked therefore

Resolved That it is the sense of this confederation that, among those states whose standards of requirements are equal or substantially the same, their licentiates by examination who can meet the moral academic medical and examining requirements of the state whose indorsement is asked, are entitled to and should be indorsed, irrespective of reciprocity

Resolved That when the standard of requirements of any two states are unequal it is in the interest of the profession that the state having the lower requirements should indorse the examined licentiates of the state having the higher requirements irrespective of reciprocity when such candidates can meet every legal and educational requirement of the indorsing state.

Resolved That reciprocity limited by statute to reciprocating states which demands equal rights and privileges in return as conditions of indorsement with the purpose of compelling recognition of its own licentiates is detrimental to and retards the progress of the profession because 1 It restricts the extension of indorsement by its limitations 2 It causes hardship to the profession because of its uncertain tenure 3 It excludes indorsement from states having higher requirements by reason of which reciprocity can not be effected 4 It refuses recognition to distinguished physicians of non reciprocating states 5 It recognizes neither the merit of a state examination nor that of the licentiate as compared with reciprocity 6 It tends to maintain standards at the level of the lowest reciprocating state and offers no inducement for a state to raise its standards above those of its reciprocating neighbors 7 It practically involves an omnibus indorsement, without inquiry as to the status of the individual candidate and without discrimination since all licentiates of a state stand legally on an equal footing 8 It is impractical for adoption by any considerable number of states, because of the difference in state laws standards and population

Resolved That reciprocity based on a voluntary agreement of state boards is like statutory reciprocity impractical because 1 There is no uniformity in state laws and no ability to enforce them 2 When differences arise between examining boards in respect to the status of colleges the grade of examinations or the eligibility of candidates rejected by one board for examination by another there is no law national interstate or state to adjust the differences or to enforce the agreement which may be broken at the pleasure of either board and without redress

Resolved, That interstate indorsement authorized by statute and exercised at the discretion of a state medical licensing board irrespective of reciprocity based on the substantial equality of educational requirements on a state examination satisfactory and approved as to kind and grade and on the individual merit and the professional qualification of the candidate for indorsement is far better than indorsement based on either statutory or voluntary reciprocity and tends more than either to further the cause of higher medical education and the autonomy of the profession throughout the country 1 It is good state policy since it neither denies citizenship nor the right to practice to any physician entitled through merit to its privileges. 2 It makes the state the sole judge of the qualifications of its licentiates by enforcing the same requirements for indorsement as for examination for license thus placing all licentiates on the same footing 3 It accepts a state examination for what it represents as an examination but not as more important than the merits and qualifications of the candidates for indorsement 4 It tends to raise and maintain a high standard of education by making a license from a state with high requirements more widely acceptable for indorsement than one from a state of low requirements and thus admits of early national application. 5 It requires legal evidence of individual merit as well as professional qualifications for approval for indorsement and this tends to reduce to a minimum the indorsement of irregular itinerant practitioners. 6 It puts a premium on character and education and renders the best practitioners eligible for indorsement in every state 7 It indorses both the state and the individual candidate and failure of a state to reciprocate therefore does not afford either a legal or valid reason for rejecting any of its licentiates who can meet every requirement of the statute 8 It may accept any of the examined licentiates of a state for indorsement or only those examined and licensed under the most recent requirements

Resolved That a state that will not indorse the examined licentiate of another state where the standards are co equal or of a state where the standards are higher stands as a hindrance to medical progress because 1 It does not recognize the efficiency once proved by examination in a state of co-equal or higher requirements 2 It limits the working sphere of the profession 3 It exacts the same requirements for license from the physician duly licensed after an examination in a co equal state and experienced by years of practice that are exacted from the inexperienced graduate

Resolved That indorsement therefore irrespective of reciprocity should be granted to examined licentiates of states whose standard of requirements is co-equal or higher when the candidate for indorsement can meet in all respects the requirements of the statute governing the practice of medicine

THE UNCONSTITUTIONALITY OF INDORSEMENT

Sault Ste Marie, Mich , Aug 1, 1904

To the Editor —The resolutions submitted by Dr Godfrey, at the meeting of the National Confederation of State Medical Examining and Licensing Medical Boards, were promptly tabled by the confederation, but, unfortunately for the cause of reciprocity, were ordered printed and distributed, with the possible effect of again clouding the reciprocal atmosphere (I see that the *New York Medical Journal* indorsed them, June 18) in an attempt to solve a simple problem by a method which is clearly unconstitutional and impracticable, and which lacks even the merit of an ordinary knowledge or understanding of the present status of medical reciprocity in the several political divisions of the United States These resolutions ignore, altogether, the fact that over a dozen of the better states are at the present time exchanging licenses through reciprocity agreements on a perfectly satisfactory and practical basis, and that any one or all of such reciprocating states, through actual experience, can testify to the incorrectness of the conclusions and deductions recorded in the resolutions mentioned

These resolutions are based on the fundamental principle that interstate reciprocity and interstate indorsement are only practical and of value when applied to those practitioners who obtained their licenses on the basis of an examination before a state board of medical examiners As this class of practitioners represents less than 10 per cent. of the reputable physicians in the United States, and include only those of recent graduation, the expressions used in the resolutions, i e, "hardship to the profession," "refuses recognition to distinguished physicians," "placing all licentiates on the same footing," etc , seem ludicrous and ironical in the extreme I would ask in all seriousness, how many of the eminent practitioners of this country have obtained their state licenses on the basis of an examination before a state medical board?

Several of the state medical boards, including that of New Jersey, are committed to the policy of recognizing for interstate exchange certificates of registration or licenses obtained solely on the basis of an examination on stated subjects before state medical boards It may be of interest to these boards to learn that any scheme of medical reciprocity which includes only licentiates who obtained their medical licenses on the basis of a state board examination, and which excludes licentiates who obtained their medical licenses on the basis of a college diploma, is unconstitutional, and unquestionably would be held so by any one of the several state supreme courts or the United States Supreme Court, for the following reasons

1 State legislatures have authority to make reasonable provision for determining the qualifications of those engaged in the practice of medicine, and in connection therewith to create a tribunal, whether called a court or a board of registration, to administer such provisions

2 State legislatures have up to a certain date provided as a qualification for registration or license subsequent to the passage of medical acts, a single examination of a certain grade, either by a state board of medical examiners or by a faculty of a medical college recognized by a board of medical registration and examination in lieu of such examination More recent legislation in many states provides, however, for a double examination for license—one by a recognized faculty, and one by a medical board

3 Up to the date of a double examination requirement by a state board, the legal status of a college faculty examination fully equals that of a state board examination

4 It is, therefore, illegal and unconstitutional for a medical board to recognize as a qualification for license a state board examination and refuse recognition as a qualification for license a recognized medical college faculty examination up to the date when the law required the double examination qualification

5 It is not legally competent for a medical board whose state law provides for medical reciprocity to adopt, even silently and without resolution, the policy of non medical reciprocity The law presumes proper action by the board in all its provisions, and boards could be compelled, through mandamus proceedings, to administer rightly a reciprocity provision equal to that of an examination provision

The legal point in the matter centers on the examination qualification as a requirement for license, and the fact that two kinds of examinations are equally recognized in law up to the date of a double examination requirement In order to understand the legal point involved, it is necessary to separate the *fact* from the *form*, the latter representing the diploma from the college and the certificate from the board, and the former representing the examination by which the diploma or certificate was obtained The form is of very minor importance and is useful only for identification purposes, but the fact (the examination) contained in the diploma or certificate is the material substance affected by reciprocity

The American Confederation of Reciprocating Examining and Licensing Medical Boards formulated the following qualifications in May, 1902, which are in harmony with the legal points raised above, and its members (fourteen in number) are exchanging licenses on the basis of these qualifications

ARTICLE II

The object of this confederation shall be to establish reciprocal relations between the medical examining and licensing boards of the states territories, districts and provinces of the United States, the purpose of which being that thoroughly worthy and well qualified physicians and surgeons, who have been legally authorized to prac tice under the laws of one of said states, territories districts or provinces may be given legal authority and be admitted to prac tice in any state territory district or province represented in this confederation without a repetition of the tests of qualification to which such practitioner has submitted

QUALIFICATION 1

A certificate of registration showing that an examination has been made by the proper board of any state, on which an average grade of not less than 75 per cent was awarded the holder thereof having been at the time of said examination the legal possessor of a diploma from a medical college in good standing in the state where reciprocal registration is sought may be accepted in lieu of examination as evidence of qualification provided that in case the scope of said examination was less than that prescribed by the state in which registration is sought the applicant may be required to submit to a supplemental examination by the board thereof in such subjects as have not been covered.

QUALIFICATION 2.

A certificate of registration or license issued by the proper board of any state may be accepted as evidence of qualification for reciprocal registration in any other state provided that the holder of such certificate had been engaged in the reputable practice of medicine in such state at least one year and also provided that the holder thereof was at the time of such registration the legal possessor of a diploma issued by a medical college in good standing in the state in which reciprocal registration is sought and that the date of such diploma was prior to the legal requirement of the legal examination test in such state.

Dr Godfrey's resolutions make much of inequality of state requirements and the difficulties to be met in adjusting them and advocates indorsement in lieu of reciprocity as a remedy Qualification 1 as quoted, provides the only legal equitable and practical methods viz. the supplemental examination

Under the provisions of Qualification 1 it matters not if the requirements of one state are very much higher than those of the other state The inequality can be adjusted equitably in every case without inflicting any hardship on the applicant, and at any time, and it allows for the raising of standards in states at such times and under such circumstances as made necessary by local conditions This qualification eliminates completely a "repetition of the tests of qualification" to which a practitioner has submitted, and this "repetition of the tests of qualification" is the sole reason given for reciprocity No reputable or worthy practitioner can possibly object to fulfilling qualifications which he has not previously fulfilled

Qualification 2 applies to those reputable practitioners who obtained their state licenses on the basis of a faculty examination (college diploma) previous to the date of the double examination requirements (college diploma and state certificate) in states Under this qualification no state is required to accept an applicant whose diploma dates subsequent to the date of the double examination test in such state In other words, the applicant, if he had applied for registration in such state at the time of his graduation, would have been accepted Therefore, the state, under Qualification 2, dates back the application The applicant in addition to a standard qualification recognized as such at the date of issue, at this time also possesses several years of practical experience, which is in itself a legal qualification asset, and has, further, been investigated and recommended by the state in which his professional work has been done

Could any provision for reciprocity be fairer, more equitable, more consistent with constitutional as well as statutory law—broad and yet conservative, insisting on an exact legal qualification at the date of registration, than Qualification 2? It includes fully 75 per cent of those practitioners to whom the benefits of practical reciprocity apply Reciprocal legislation, which provides only for the present and future practitioner and ignores the older and experienced practitioner for the reason that the latter has not obtained his license through a state board examination, is not only irrelevant and unjust, but is also unconstitutional. The only practitioners excluded from medical reciprocity under Qualifications 1 and 2, in addition to practitioners not indorsed by state boards as moral and reputable, are those practitioners who obtained their licenses through a re-registration clause on the qualification of "years of practice" and those graduates of reputable colleges who registered under an exemption clause which permits graduates of colleges in the state responsible for the act to register without examination subsequent to the time of the double examination requirement in such state, and where all graduates from without the state are required to take the double examination requirement.

The above practitioners represent about 10 per cent of the total practitioners of the United States and are not legally entitled to consideration, furthermore, such exemptions are unconstitutional and probably will be declared so in the near future by competent authority, and those practitioners who obtained their licenses through such exemption will face the possibility of being summoned before boards to show cause why their certificates should not be cancelled from the fact that they have been issued through error

No attempt has been made, as far as I am aware, to criticise adversely Qualifications 1 or 2 The fact that they have been endorsed and made active by several of the leading states is sufficient reason for their being considered seriously, and objected to if they do not fulfill exactly the purposes which created them It is strange and unexplainable that in the matter of medical reciprocity eastern state medical boards are not only inactive and unprogressive but fail to appreciate and to accept the practical results which have set aside all their objections against reciprocity

A meeting of the American Confederation will be held at St Louis the last Wednesday in October, and it is to be hoped that the majority of eastern boards will demonstrate their reciprocity consistency by sending fully accredited delegates with power to act to this meeting B D Harison,
Secretary American Confederation of Reciprocating Examining and Licensing Medical Boards, and Secretary Michigan State Board of Registration in Medicine

List of Tuberculosis Hospitals

New York City, Aug 1, 1904

To the Editor —The National Association for the Study and Prevention of Tuberculosis, in co operation with the Committee on the Prevention of Tuberculosis of the Charity Organization Society of New York City, is preparing a directory of the various agencies existing and projected, in the United States and Canada, which care for persons suffering from any form of tuberculosis or which work in any way for its restriction

This directory will include information in regard to hospitals, sanatoria, dispensaries and camps especially designed for tuberculous patients or with especial provision for them, whether public or private, insane hospitals and prisons in which special provision is made for the tuberculous inmates, state commissions and private societies formed for the purpose of investigation or of diffusing information, and a summary of the efforts being made by the boards of health in the principal cities

A tentative list of institutions is given below It is desired to make this directory as complete and as accurate as possible Any additional addresses, therefore, or any reasons why institutions that are included should be omitted, will be welcomed Information about any institution will be considered confidential, if so desired Communications should be addressed

How to Take Notes on Lectures

Denver, Aug 4, 1904

To the Editor —The note-book in the hands of the student comes down to us from the days when medical books were few and costly In the Alumni Register of the University of Pennsylvania for June is the account of the expenses of a medical student of one hundred years ago Among the items in this account we find 'Bell's Anatomy, $22," 'Chaptal's Chemistry, neatly bound, $5 75," and "Barton's Elements of Botany, $6 00"

But in this day, when almost every teacher has his own text book or volume of published lectures, the student no longer needs to provide his medical library for future reference as he sits listening to lecture or clinic The library so provided, judged by modern standards, is sure to be a very poor one But although the note-books when finished may be worthless, a certain amount of advantage may be gained in the writing of them When kept in the usual manner, however, this is more than balanced by the disadvantage of the interruption of thought and attention that comes from writing down the sentence which has been spoken, while the mind should be wholly given to the appreciation of what is then being said

If note-books are to be kept they should be written outside of the lecture room Briefly, the plan is to concentrate the whole attention on what the lecturer is saying, making a little special effort to notice the principal divisions or headings of his lecture and the order in which they are presented Then, shortly after the lecture (at first it is best to do it immediately, and generally before sleeping) the notes are to be written up from memory If the teacher makes a practice of summarizing each day, at the beginning of his lecture, the matters presented the day before, the student may compare this summary with his notes But when the lecture of the day begins the notes should be laid entirely aside.

This plan has been tried often enough to demonstrate that it is perfectly practicable for any student who has sufficient intelligence and preliminary training to profit by the lecture he listens to The note-books produced in this way will be found to contain quite as much of value as those that are immediately jotted down, except in the matter of formulas and statistics, which are much better left to the text-books They will show a better selection of material, a better appreciation of relative importance, than is possible with the immediate jottings But the most important result of the system is that more material and better selected material is left in the memory of the student. The systematic review of the lecture within a few hours after hearing it that this plan compels doubles the value of the instruction received

Of course, a set of note books so prepared, and the training incident to their production, cost some effort, but there is no direction in which the same mental effort can be expended with greater resulting benefit More important than the mere training of memory is the practice in selective judgment of what is brought before the mind This plan, carried out through the medical course, will enable one readily to report in fair abstract, any paper or address listened to, or to gather and hold in mind the important points for future discussion What has been said above does not, of course, apply to the note-book in the dissecting room or laboratory, where facts observed may be noted down, especially by means of diagrams and sketches, with the greatest benefit

Edward Jackson

The Revival of Didactic Instruction

Memphis, Tenn , July 25, 1904

To the Editor —The didactic lecture hall, the recitation room, the clinical amphitheater, the hospital wards and the laboratories should all be utilized to the fullest extent in teaching modern medicine I regret to note the sentiment prevailing in some of our great schools against didactic work No student can read unless he first learns his alphabet Nor can he solve a problem in mathematics unless he knows his figures He can not parse a sentence in English or solve a problem until he has been thoroughly grounded in the rules governing each case

The didactic lecture is the alphabet, the unit one, the rules in teaching medicine Let the didactic professor preach typhoid fever in the most forcible manner, then let the clinical professor teach typhoid fever in the hospital wards I am a hearty champion of didactic work along with clinical Medical schools to day need more men like Pepper, DaCosta, Flint and Gross We need men of culture, men of personality, men with powers of expression, men with clinical instinct, men who have acute observation as teachers Politics is reigning supreme in many of our very best universities In my opinion one of the oldest and greatest universities in this country is absolutely honey combed with politics Schools which are liberally endowed, and which should set the standard of medical education should in every sense eliminate politics for ever Let our schools, whether they are endowed or not, select their teachers with reference to their capacities and not according to their financial or family pull No doubt there is too much technical work Our pathologists and bacteriologists should adopt a better nomenclature The terms now in vogue are harder to memorize and to remember than the muscles of the forearm in Gray's Anatomy There is too much ornamentation of nonsensical terms, and not enough dress of good, plain English

The recitation method is a good one and should be encouraged It stimulates the student body to action and brings him in a more intimate touch with his teacher A more cordial relationship should exist between student and professor **Frank Jones**

The Clinical Teaching Pendulum Has Swung Too Far

Philadelphia, July 29, 1904

To the Editor —My experience with students has convinced me that we have swung a little too far in the direction of clinical teaching, that at the present time we are giving them too few systematic ideas in regard to disease The picture of disease as presented to them in a single clinical case may show but a few of the characteristic evidences of the malady, and may differ widely from the usual and ordinary The student needs in the first place to acquire a thorough outline of the average case, after that he can apply with greater advantage his knowledge to the individual The clinical lecturer as a rule lays especial emphasis on the symptoms of the case before him which may be very misleading, or at least, imperfect

De Forest Willard

Queries and Minor Notes.

UNINTENTIONAL TRESPASS

———, Texas, Aug 2 1904

To the Editor —Dr A was attending Mr X who had parenchymatous nephritis The case was serious and Dr A called Dr B in consultation, after which they advised Mr X to spend the summer at some watering place referring him to physicians there While at the watering place he was treated by the physicians to whom he was referred After a few weeks he returned home and continued the treatment recommended by the latter He was suddenly taken with severe dyspnea and sent for Dr B at 2 o'clock in the morning Dr B went and was asked to continue in treatment of the case as they could not now return to the watering place Nothing was said about Dr A Dr B was under the impression that Dr A had relinquished the case when Mr X went to the watering place, or he would never have taken it Dr A is now offended and Dr B wishes to know if he had committed an error in taking the case. He is very desirous to have the matter adjusted, as the mistake was not made from malice, but only from a wrong impression of the situation **Enquirer.**

Answer —The conduct of physicians in such cases, according to the Code of Ethics, is to be based on the golden rule This will lead to careful inquiry as to the rights of other physicians to avoid unintentional trespass, even though a patient may consider that for him to summon a new attendant is *ipso facto* a discharge of the old The physician can not always consider it so When one makes an error or offends a confrère in the way described, one should frankly explain and apologize, and even give up the case if the patient elects because the loss of a patient from one s clientele is a small matter compared with the loss of professional fellowship and good feeling toward a confrère For the same reason the physician represented in this case by Dr A should exercise charity and heartily accept an apology when offered If he knows his friend to be an honorable physician, let him think that he lost the case through his own inferiority rather than through any dishonorable action on the part of his friend

THE LIMITATIONS OF GRATUITOUS SERVICES TO PHYSICIANS DEPENDANTS

———, ———, Aug 5, 1904

To the Editor —Will you kindly reply to the following query through The Journal? A student, the son of a homeopathic physician of a distant town and a complete stranger to me, contracted chancroids while attending school some distance from here He consulted me and was treated for several weeks. The severity of the case and the development of chancroidal bubo necessitated several time-consuming visits and surgical treatment. An anxious impersonal letter to the attending physician was replied to by me, stating the boy s exact condition, and that he would be carefully looked after No reply to this was received The young man was emphatic in his statements that all would be paid for, and, indeed, a small part was paid The bill was sent to him several times, and several months ago to the father, without response Now, what is the proper and respectful course for me to pursue? Surely no self respecting physician would expect another to do that kind of business for his erring son for nothing **Y**

Answer —The Principles of Ethics advise all physicians to render gratuitous service to any other 'practicing physician and his immediate family dependants In addition, it is suggested that an obligation lies on a physician in comfortable circumstances to recompense a colleague for professional service requiring sacrifice of considerable time In the case submitted, it is perfectly clear that the homeopathic physician is under real obligation to our correspondent and should be ready to recompense him in suitable amount —something less than ordinary charge in similar cases in that locality As to the proper course for our correspondent now to pursue, we can hardly advise that is so largely a matter of personal taste and inclination, and of opportunity Certainly it would not quite be wise to risk loss of prestige by publicly pressing such a claim, however aggravated the circumstances might be

SLOW PULSE IN TYPHOID

Edmond, Okla , July 27, 1904

To the Editor —Will you please explain the cause of slow pulse frequently found in typhoid fever? I have seen three or four cases during the last year with pulse ranging from 40 to 70 or 80, with a temperature of 101 to 103 Text books speak of the slow pulse but do not give its cause Do you suppose the typhoid toxin influences the pneumogastric nerve to the production of this condition?

T H Flesher M D

Answer.—Your observation of the slow pulse in typhoid fever is as you say a confirmation of the statement made in many text books But it is well to emphasize the value of the slow pulse in spite of high fever because in many books no mention of the fact is made, and too often the practitioner overlooks what is really a valuable help in the matter of diagnosis and prognosis As is well known, too the pulse of the *convalescent* typhoid is apt to be slow While this slow pulse is probably commoner after typhoid than after other febrile diseases it is seen after other infections and is an example of the post febrile bradycardia, or bradycardia of convalescence of Huchard and others The explanation of this phenomenon is largely a matter of speculation It may be as suggested, due to an involvement of the vagus nerve or its center, but it is more likely we think due to the action of the toxin on the heart muscle itself Many of the so called neurotic affections of the heart are in reality myocardial in origin and while the influence of the pneumogastric and of the intrinsic cardiac nerve fibers and ganglia can not be excluded one would feel inclined to look on the bradycardia as in large measure due to the effect of the typhoid infection on the heart itself That the heart muscle is affected in typhoid sharing in the acute parenchymatous degeneration of the viscera is well known and cardiac weakness and instability of its muscular power is often shown during convalescence when a patient whose pulse while in bed was perhaps only 50 or 60 has on first getting up a pulse of 100 or 120 In all this question there is an unknown element that is not explained and that is why the poison of typhoid generally causes a slow pulse while that of some other disease e g scarlet fever causes a rapid pulse We may speak of a selective action of these toxins as we do of drugs, and of their specific effect yet there is still left much that is not quite clear

REMOVAL OF SUPERFLUOUS HAIR

——, Ga., July 22 1904

To the Editor —Is there a harmless prescription or means for the removal of superfluous hair—for instance under the arms, or on the upper lip of a woman" S

Answer —Permanent removal of moderate hair growth on women s faces can be effected by electrolysis The operation is permanent in its effects but as each hair must be treated individually it is only practicable in cases in which the hairs are coarse and not too numerous The object of the electrolytic operation is to destroy the papilla and lower part of the follicle. For this purpose are required a galvanic battery of 10 to 30 cells an extremely fine needle needle holder an electrode a rheostat a milliamperemeter and the ordinary cells The strength of current required is from ½ to 1½ milliamperes The operation should be conducted with strict aseptic precautions The *x* rays have also been used in this class of cases, but with unsatisfactory results. One of the best depilatories (as suggested by Duhring) consists of from 2 to 4 drams of barium sulphid with enough zinc oxid and starch to make an ounce. The sulphid should be well and freshly made and kept tightly corked otherwise its action is unsatisfactory At the time of application sufficient water is added to make a paste which is thickly spread over the part and allowed to remain for from one to two minutes and then scraped off and a soothing ointment or dusting powder applied The application is repeated every week or two or as soon as the hair has reappeared

PHYSICIANS CARDS IN NEWSPAPERS

—— Ill. July 21 1904

To the Editor —Would the following card be unethical in a newspaper in a small town where one is beginning a practice?

Office Hours
8 to 10 a. m 1 to 3 p m 6 30 to 7 30 p m
JOHN R. DOE
Physician and Surgeon
Corner of Vine and Cherry streets Corn Ill
Special attention given to microscopic and chemical analysis
W

Answer.—The question raised is one of expediency rather than of ethics. Publishing a simple professional card giving name address and office hours is permissible though in most parts of the country it is avoided as a matter of taste Specifically the card submitted appears rather pointless The general public does not go to a physician for microscopic and chemical analysis. In many places a young physician can pick up a little money doing this work for other and busier physicians. In seeking that patronage, however one should call directly on the other physicians and solicit their favor as they will not respond to a newspaper card If however a physician advertises in the way mentioned with the idea of impressing the public with his superior methods of diagnosis etc., the matter becomes objectionable

—— Iowa Aug 4 1904

To the Editor —When a physician puts his professional card in a daily or weekly paper would there be any objection to his embodying in that card his place of graduation and hospital connections? The point came to my attention the other day and I know that many physicians in good standing do so H

Answer.—While there is no rule against inserting college and hospital connections in a professional card published in a newspaper there is, nevertheless a very strong feeling in the profession that the inclusion of such data constitutes objectionable advertising The man who thus parades his attainments may not in some places be ostracised professionally but he certainly in most localities would be running very great risk of attracting strong professional disfavor Our advice certainly is that it would be wiser to avoid such a practice

DRY HOT AIR APPARATUS

Burr Oak Ind July 21 1904

To the Editor —Can you, or any of the medical fraternity tell us how much value there is in the dry hot air apparatus that is being so extensively advertised at the present time? Is there any good reliable book on the subject? If so what? Literature seems very deficient along this line, and while a great deal of it seems to appeal to reason, we would like to know what is the prevalent opinion regarding it. E W Reeves M D

Answer.—The dry hot air apparatus has a distinct field of usefulness in many of the chronic joint affections particularly those of a so-called rheumatic nature. The cases should be selected with care. Arthritis deformans is reported as being particularly benefited. A number of reliable articles have appeared from time to time in the literature. (For example, see The Journal July 4, 1903 p 60 ¶146) A good work on the subject is that by Skinner (price $2) obtainable through any large book firm

Marriages.

Ray Ash, M.D , to Miss Gail Arnold, both of Ashland, Ohio, July 26

Charles K Clarke, M.D , to Miss Teresa Gallagher, both of Kingston, Ont

Gerald B Webb, M D , to Miss Varina Davis Hayes, both of Colorado Springs, Colo

Harry Wayble, M D , Cincinnati, to Miss Anna Brothers of Newport, Ky , July 25

J E Schein, M.D , to Miss Laura M Phillipson, both of Oshkosh, Wis , July 27

Eugene H Bullock, M.D , to Miss Beulah De Vorss, both of St Joseph, Mo , July 25

Louis S Walton, M.D , to Miss Angeline McCray, both of Pittsburg, Pa , August 2

Clayton B Conwell, M.D , Cincinnati, to Miss Sarah W Jones of Riverside, Ohio

Francis E Shine, M D , Bisbee, Ariz , to Miss Barker of Toronto, Ont , August 2

Robert M Rankin, M D , Covington, Ky , to Miss Delia Johnson of Barboursville, Ky , July 24

J Samuel Shaffer, M D , to Miss Christobel Ort, both of Montgomery, W Va., August 2

Isidor Clarence Smullyan, M.D , to Miss Sarah Wilensky, both of Atlanta, Ga., August 2

Arthur Field Lindley, M.D , New York City, to Miss Elinor Levering, at Baltimore, July 30, 1904

Edward Logan Monroe, M.D , to Miss Grace Cecilia Underhill, both of Jacksonville, Fla , August 3

Anton H Vorwerk, M D , Burlington, Iowa, to Miss Katherine Winkle of Bancroft, Iowa, July 27

Max G Schlapp, M D , New York City, to Mrs Grovene Vail Converse, in London, England, July 30

Chesley Lanier Carter, M.D , to Miss Mabel Moon, both of Chatham, Va , at Washington, D C , July 25

Julius M. Purnell, M D , acting assistant surgeon, U S Army, to Miss Edith Terry of Louisville, Ky , August 4

Deaths.

Edward H. Hill, M D Harvard University Medical School, Boston, 1867, founder of the Central Maine General Hospital Association, formerly president of the Maine Medical Association, for several years president of the Androscoggin County Medical Society, died at his home in Lewiston, July 17, after an illness of several years from spinal disease, aged 60

John Turnbull, M D Jefferson Medical College, Philadelphia, 1863, of Bellbrook, Ohio, assistant surgeon to the Sixty fifth Ohio Volunteer Infantry, and later surgeon to the One Hundred and Fifth Ohio Volunteer Infantry, died at St Elizabeth's Hospital, Xenia, Ohio, July 19, five days after an operation for the removal of gallstones, aged 64

John Cooper, M D Department of Medicine of the University of Pennsylvania, Philadelphia, 1857, surgeon in the Army, as a prisoner of war in New Orleans, and after his exchange, in connection with the Seventeenth Army Corps, died at his home in Buffalo, N Y , July 11, from paralysis, aged 71

William H Hanscom, M D College of Medicine and Surgery of the University of Minnesota, Minneapolis 1889, for 10 years medical inspector for the Department of Health of Minneapolis, died at his home in South Minneapolis, July 16, from dropsy, after an illness of five months, aged 37

James W Wilson, M D Jefferson Medical College, Philadelphia, 1837, some time president of the Sandusky County Medical Society, and a member of the Ohio State Medical Society, who retired from active practice in 1858, died at his home in Fremont, Ohio, July 21, aged 88

Charles Fletcher Sumner, M.D College of Physicians of the Western District of New York, Fairfield, 1840, twice a member of the General Assembly, medical examiner of Bolton, Conn , and for 62 years a practitioner of that place, died at his home, July 12, from pneumonia, aged 87

Ernest A Taylor, M.D Missouri Medical College, St Louis, 1865, surgeon to the Seventh Missouri Cavalry in the Civil War, for five terms coroner of Rena County, Kan , died at his home in Hutchinson, July 20, after a short illness, aged 70

John L Mitchell, M D College of Physicians and Surgeons in the City of New York, 1845 a member of the Jackson County (Mich) Medical Society for 25 years, died at his home in Jackson, July 10, after a prolonged illness, aged 81

Helen W Webster, M D New England Female Medical College, Boston, a nurse during the Civil War, for eight years resident physician at Vassar College, Poughkeepsie, N Y, died at her home in New Bedford, Mass, July 19, aged 67

D F McCrimmon, M D Atlanta (Ga) Medical College of Rochelle, Ga, formerly representative from Wilcox County in the state legislature, died at the State Sanitarium, Milledgeville, July 15, after an illness of several months

Henry D Green, M D Medical Department of the University of the South, Sewanee, Tenn, 1900, of Atlanta, Ga, was struck by a car near the World's Fair, St Louis, July 29, and died a few minutes later, aged 25

Isidor H Jacob, M D University of Würzburg, Germany, 1898, of New York City, one of the promoters of the Brooklyn Jewish Hospital, died in the German Hospital, New York City, July 18, after a prolonged illness

Columbus N Warren, M D Starling Medical College, Columbus, Ohio, 1889, of Harrietsville, Ohio, died suddenly while making a professional call near that place, from angina pectoris, July 26, aged 38

Otis H Johnson, M D Harvard University Medical School, Boston, 1866, of Haverhill, Mass, died at the Hale Hospital in that city, July 16, from diabetic gangrene, after amputation of the right leg, aged 63

Gresham P Williams, M D Hospital College of Medicine, Louisville, Ky, 1891, Medical College of Ohio, Cincinnati, 1867, died at his home in Huntingburg, Ind, July 12, after a short illness, aged 60

Robert Macdonald Kippen, M D College of Physicians and Surgeons of Ontario, Toronto, 1900, died recently and was buried from the residence of his father in London, Ont, July 18

A Clarence Bartlett, M D Medical College of Ohio, Cincinnati, 1880, died at his home in New Castle, Ind, July 10, from cancer of the intestines after an illness of two years, aged 47

State Boards of Registration.

Other Reports—This issue of The Journal has room for but a few reports of state boards Similar reports appear from week to week In the last issue, August 6, reports were given from the states of Delaware, Illinois, Massachusetts, Michigan, Minnesota, North Dakota, Ohio, South Carolina and Texas The last mentioned report included the 125 questions asked on 13 subjects

Rhode Island July Report—Dr G T Swartz, secretary of the Rhode Island State Board of Health, reports written examination held at Providence, July 7 and 8, 1904 The number of subjects examined in was 7, total questions asked, 70, and percentage required to pass, 75 The total number examined was 28, of whom 25 passed and 3 failed The following colleges were represented

PASSED

Medical Organization.

Georgia

Sumter County Medical Society —This society was organized at Americus, July 27, with an initial membership of 22, and the following officers Dr F A Thomas, Americus, president, and Dr Frank L Cato, Jr, De Soto, secretary

Illinois.

Piatt County Medical Society —Under this title the physicians of Piatt County have recently organized

Illinois Fifth District Medical Society —At the one hundred and tenth quarterly meeting of the Brainard District Medical Society, held in Bloomington, Ill, July 28, Councilor Dr J Whitefield, South Bloomington, of the Fifth District, made an address on medical organization, and presented the standard plan The society, by vote, re organized in accordance with the plan By the new districting, Morgan and Cass counties are transferred from the Fifth to the Sixth District

Michigan.

Muskegon County Medical Society —This society, whose preliminary meeting for organization was reported in The Journal of July 30, page, 344, met July 15, perfected its organization on the standard plan, and elected the following officers Dr George S Williams, president, Dr Sigmund Block, vice president, Dr Emory L Niskern, secretary, and Dr Jacob, Oosting, treasurer, all of Muskegon

Upper Peninsula Medical Society of the Twelfth District —At the tenth annual meeting of the Upper Peninsula Medical Society, held in Marquette, July 21 and 22, the society was reorganized on the standard plan, and the following officers were elected Dr Edward H. Flynn, Marquette, president, Dr Elmer D Gardner, Hancock, vice president, and Dr S Edwin Cruse, Iron Mountain, secretary and treasurer The next meeting will be held at Hancock

Missouri.

Bates County Medical Society —This society was organized in Butler, July 1, by Dr M P Overholzer, Harrisonville, with the following officers President, Dr Alva E Lyle, Butler, vice president, Dr Edward G Zey, Butler, and secretary and treasurer, Dr Edward N Chastain, Rich Hill

New Jersey

Italian American Medical Society of Essex County —On July 28 the Italian physicians of Essex County effected an organization with the following temporary officers Dr Joseph M. Malatesta, Newark, president, and Dr C C Berardinelli, secretary

Ohio

Mahoning County Medical Society —About 20 physicians of the county met at Youngstown, July 19, and, with the aid of Dr T Clark Miller, Massillon, councilor for the Sixth District, reorganized this society on the standard plan Election of officers was deferred until the January meeting

South Carolina.

Edgefield County Medical Association —This association was recently organized for Edgefield County with the following officers President, Dr J Hammond Carmichael, Pleasant Lane, vice president, Dr J M. Rushton, Johnston, secretary, Dr J G Edwards, and treasurer, Dr J N Crofton, Colliers

Texas.

South Texas Medical Association —At the semi annual meeting held in Houston, June 22 and 23, the following resolution, offered by Dr Walter Shropshire, Yoakum, was adopted on motion of Dr Robert W Knox, Houston

Whereas The successful organization of the whole medical profession of Texas as contemplated by our state association and is now being prosecuted, is to some extent handicapped by the indiscriminate membership of the large district medical associations, be it

Resolved That the membership of the South Texas Medical Association be restricted to members of societies that are chartered by and are branches of the Texas State Association. Further that so soon as the state association so directs, this association will become one of its district associations to represent it in the South Texas or Ninth Councilor District, according to the plan of recent organization of the state medical association.

The following officers were then elected Dr John T Moore, Galveston, president, Dr Sofie Herzog, Brazoria, vice-president, and Dr Edward J Hamilton, Houston, secretary and treasurer

MEDICAL SCHOOLS OF THE UNITED STATES

Below is given a brief description of every college in the United States that is legally chartered to confer the degree of doctor of medicine, and whose diploma is recognized by at least one state licensing board The list includes the sectarian as well as the regular colleges, as their graduates are physicians in the eyes of the law The information given is, as a rule, obtained from the catalogues and has been submitted to the dean of each school for his inspection and approval Colleges which belong to the American or the Southern Medical College Association or other organization of colleges have requirements for admission of students according to the rules of these associations, unless their requirements are higher, in which case a statement is made to that effect Extracts from these rules are given at the close of the list of colleges

ALABAMA

Alabama, population 1,828,697, has two medical colleges, the Medical College of Alabama and the Birmingham Medical College, located in Mobile and in Birmingham The population of each city is over 38,000 and board and room may be obtained for from $12 to $20 per month

Mobile.

Medical College of Alabama —This is the Medical Department of the University of Alabama organized in 1859 The City Hospital furnishes free clinical material The faculty consists of 9 professors and 12 lecturers 21 in all It is well equipped with building laboratories dispensary etc It is a member of the Southern Medical College Association The course of study covers four years of six months each The total fees for each of the first three years is $100 for the fourth year $125 The Dean is Dr George E Ketchum Total registration 1903 4 107, graduates, 35 The thirty ninth session will begin Oct 7, 1904, and will close April 1, 1905

Birmingham

Birmingham Medical College —This school was incorporated in 1894 and is situated in Birmingham a manufacturing town of 38 415 The clinical advantages are good The Hillman St Vincent s Pratt and County hospitals are accessible to the students. The other school, the Sewanee Medical College is located at Sewanee a mountain town of 1,200 people

Nashville

University of Nashville Medical Department—This school established in 1850 has a faculty of 13 professors and 14 lecturers assistants etc in all 27 This school is a member of the Southern Medical College Association *The course of study covers four* years of twenty six weeks each The total fees for each of the four years is $65 The Dean is Dr William G Ewing Total en*rolment for* 1903-4 was 301 graduates 41 The next session begins Oct 1 1904 and ends June 30 1905

Vanderbilt University Medical Department—This school was founded in 1874 and in 1895 when *the present medical building* was completed the course was extended *the standard raised* and the present faculty of 35 consisting of 18 professors and 17 associates lecturers etc was *appointed* The school is a member of the Southern Medical College Association The course covers four years of six months each The total fees for the first three years are $105 each and $130 for the fourth year The Dean is Dr William L Dudley Total enrolment for 1902 3 was 168 graduates 34 The next session begins Oct 3 1904 and ends April 1905

University of Tennessee Medical Department—This was organized in 1876 as the Nashville Medical College Its present relations were assumed in 1879 The faculty is composed of 14 professors and 14 lecturers assistants etc 28 in all The school is a member of the Southern Medical College Association The course of study includes work for four years of six months each The total fees for each of the first three years are $90 and $65 for the fourth year The Dean is Dr Paul F Eve 614 Broad St Total enrolment for 1903 4 was 154 students graduates 30 The next session begins Oct 3 1904 and ends April 1905

Meharry Medical College—Colored This school was organized in 1876 as the Medical Department of Central Tennessee College now Walden University for the purpose of furnishing to the colored people of the South an opportunity of obtaining a *medical* education ' The faculty is made up of 10 professors and 11 instructors demonstrators etc 21 in all The work embraces a four year graded course six months to the year *The total fees for* the first three years are $40 each and $50 for the fourth year The Dean is Dr G W Hubbard Total registration for 1903 4 was 287, graduates 57 The twenty ninth session begins Sept 1 1904 and ends March 1, 1905

Southwestern Presbyterian University Medical Department—This department was established a year ago Dr J W Brandau is Dean and about sixteen members of the faculty were chosen No further steps have been taken toward beginning work and the probability is *that nothing will ever be done*

Knoxville

Tennessee Medical College—This school was organized in 1889, and has a *faculty of 13 professors* and 7 assistants 20 in all A new building with large and well fitted laboratories has been completed City General Hospital and a free dispensary supply material for study of clinical cases This school is a member of the Southern Medical College Association The curriculum includes graded work for four years of seven months each Fees Matriculation, $5 annual fee $50, graduation fee $25 The Secretary is Dr S L Jones *Total* number of students for 1903 4 was 87, graduates 10 The sixteenth session begins Nov 1, 1904 and closes May 23, 1905

Knoxville Medical College—Colored. This school was established in 1900 *following* the discontinuance *of* the Medical Department of Knoxville College, organized in 1895 The teaching force comprises 21 The course covers four years of six months each Fees First year $42 second $37, third, $30, and $40 for the fourth year The Secretary is Dr H M Green Total number *of students for 1903-4* was 30 graduates 8 The next session opens Dec 1 1904, and closes May 30 1905

Chattanooga

Chattanooga Medical College—This is the Medical Department of Grant University, and was organized in 1889 The faculty consists of 10 professors and 18 instructors demonstrators etc, total 28 Adequate *clinical facilities are afforded by the* wards of Baroness Erlanger Hospital a county asylum, an outdoor clinic maintained in the college building and all material furnished by the city physician s office which the faculty desire to utilize The scholastic requirements are those of the Association *of Southern Medical Colleges and involve* a strictly graded course covering four years of six months each The total fees approximate $60 each session The trustees materially added to the general *facilities of* the institution *by the erection of* another fine four story building of brick and stone for the medical department about a year ago wherein much modern and elaborate equipment has been installed The Dean is Dr E A Corleigh The *total* enrolment for the session of 1903 4 was 164, of which 37 graduated The sixteenth annual term opens Oct 6 1904 and ends about April 15 1905

Chattanooga National Medical College.—Colored This was organized in 1898 and claims a teaching force of 19 The course covers four years of seven and a half months each *The total fees* are $50 each year with an additional graduation fee of $20 Total enrolment for 1903 4 was 9 graduates 1 The Dean is Dr T W Haigler 602 E 8th St The next session begins Sept. 2, 1904 and ends April 28 1905

Memphis

Memphis Hospital Medical College—This school organized in 1878 has a *faculty of 10 professors and 18 assistants* beside quiz masters Excellent clinical facilities are furnished by the City Hospital Presbyterian Hospital St Joseph s Hospital and the *East End Dispensary* the latter being located in the college building The course includes graded work for four years of six months each The total fees for the first three years are $65 for the fourth $90 The Dean is Dr W B Rogers Total registration for 1903 4 was 566 graduates 153 The twenty fifth annual session will begin Oct 1, 1904, and close April 30 1905

Jackson

Medical Department of the University of West Tennessee *—Colored* This school organized in 1900 has a *faculty of* 11 The course is four years of seven months each The fees are $40 per year graduation, $10 extra. Registration 1903 4 35 graduates 13 The next session opens Sept 12 1904

Sewanee

Medical Department of the University of the South (Sewanee Medical College)—This school was organized in 1891 and has a faculty of 22 It is a member of the Southern Medical College Association The course is *four years of six months* each The fees are $65 for each of the first two years $55 for the third and $80 for the last year The Dean is Dr John S Cain Total enrolment for 1903 4 was 148 graduates 24 The thirteenth session commenced April 1904, and will close October 25 1904

TEXAS

Texas, population 3,048,710, has eight *medical* colleges The University of Texas *Department of Medicine* is *located* at Galveston, a city of 37,789 *inhabitants* Good board and room can be procured *for from $15 to $20* a month

The Medical Department of Fort Worth University is at Fort Worth, population 35,000 The cost of board and room in that city is *from $12 to $15* a month

The Baylor University College of Medicine, the Dallas Medical College, the Medical Department of Southwestern University and the Physio Medical College of Texas are situated in *Dallas, population* 55,000

Galveston.

University of Texas Medical Department—This department of the State University was *organized* in 1891 and has a faculty of 26 The John Sealy Hospital also having an outdoor department and St Mary's Infirmary supply good material for clinical study The requirements for admission are proof, either by certificate or examination that the candidate is *sufficiently proficient* in English including grammar composition and rhetoric mathematics through plane geometry and algebra including quadratics and general history The curriculum embraces graded work for four years of eight months each Laboratories of chemistry, physiology anatomy, pathology bacteriology histology pharmacy *and clinical* medicine, *completely* equipped for practical work by students Fees to residents of the state First year $50, second and third, each $20 and $5 for the fourth Non residents *of* the state are required to pay an additional fee of $30 each year The President is Dr William L Prather Total registration for 1903-4 was 172 graduates, 23 The next sess*ion* begins Oct 3 1904 and ends May 31 *1905*

Ft Worth.

Medical Department of Fort Worth University —This school was organized in 1894 and has a faculty of 15 professors and 17 lecturers, assistants etc in all 32 Clinical facilities are supplied by St Joseph s Hospital with 200 beds the Benevolent Home containing 75 beds the Delia Collins Rescue Home having 50 beds and a college dispensary The school is a member of the Southern Medical College Association The course covers four years of six months each The total fees for each of the first three years are $75 and $100 for the fourth year The Dean is Dr Bacon Saunders The total enrolment for 1903-4 was 106 graduates 9 The next session opens Oct 1 1904 and closes April 7 1905

Dallas.

Baylor University College of Medicine —This is a new name for the University of Dallas Medical Department which was organized in 1901 In June 1903 it became the Medical Department of Baylor University at Waco The faculty numbers 14 professors and 16 assistants, total 30 Parkland Hospital with 90 beds St Paul s Sanitarium Baptist Memorial Hospital and a college dispensary and hospital are utilized for clinical study The course covers four years of six months each The school is a member of the Association of Southern Medical Colleges The fees are $75 for each of the four years with a matriculation fee of $5 paid once and a graduation fee of $25 The Dean is Dr E H Cary Total registration for 1903 4 was 68 graduates, 12 The next session opens Oct 1 1904, and closes April 5 1905

Bell Medical College —This school was founded in 1903 by Dr Arthur C Bell its present Dean It has a total teaching staff of 15 The course of instruction extends over four years of six months each The requirements for admission are the same as those prescribed by the Association of Southern Medical Colleges. Clinical instruction is given in the City Hospital St Paul Sanitarium and the college dispensary The fees for the first three years are $80 and $105 for the fourth year Total registration for 1903-4 72 graduates 9 The next session begins Oct 3 1904 and closes April 1 1905

Dallas Medical College —This school was the Medical Department of Trinity University but this relation has been severed It has a teaching staff of 9 professors and 21 lecturers and demonstrators a total of 30 The course covers four years of six months each The Dean is Dr Hugh L McNew Total registration for 1903 4 was 252 graduates 2 The next session opens about Oct. 1 1904 and closes about April 1 1905

Physio Medical College of Texas —This college was organized in 1902 It has a faculty of 24 professors and 4 assistants total 28 The course is four years of twenty six weeks each The fees are, first year $70 fourth year $85 other years $65 Enrolment 1903 4 21 no graduates The Secretary is Dr R I Spann The next session opens Nov 1 1904 and closes about April 1 1905

Southwestern University Medical College.—This is the Medical Department of Southwestern University and was organized in June, 1903 It has a faculty of 31 professors and 8 instructors total 39 The course of instruction is graded and covers four years Requirements for admission are equivalent to those prescribed by the Association of American Medical Colleges The fees are Matriculation $5 paid once annual tuition $75 graduation $25 The hospitals represented by the faculty and open for clinical teaching are St Paul s Sanitarium City Hospital Children's Home, Rescue Home Woman s Home St Joseph Orphanage St Matthew s Home for Children Dr H K Leake s Private Infirmary Out Door Clinic of the Settlement Home and Presbyterian Home for Children The Dean is Dr John O Mc Reynolds Total registration 1903 4 was 38 graduates 11 The second session opens Oct 1 1903 and closes April 3 1905

Texarkana

Gate City Medical College —The length of each course is seven months The faculty numbers 20 professors and assistants Registration 1903-4 84 graduates 26 The Dean is Dr J W Decker The next session begins Oct. 1 1904 and ends May 1 1905

VERMONT

Vermont, population 343,641, has one medical school located at Burlington, a town of about 20,000 people Board and room costs from $3 50 to $5 a week

Burlington

Medical Department University of Vermont —This school was organized in 1822 but suspended from 1836 until 1854 when it was reorganized The faculty consists of 19 professors and 23 assistants instructors etc in all 42 The Mary Fletcher Hospital and a free dispensary furnish material for clinical instruction. Applicants for admission must be graduates of a four year high school course or take an examination to show equivalent educational qualifications The laboratory and lecture-room space and equipment are good A new and commodious college building is in process of construction The course of study embraces graded work for four years of seven months each The total fees for each of the first three years are $115 and $140 for the fourth year The Dean is Dr H C Tinkham Secretary Dr B J Andrews. Total registration of students for 1903-4 was 225 graduates, 55 The fifty second session begins Nov 26 1904 and ends June 28 1905

VIRGINIA.

Virginia, population 1,854,184, has three medical colleges, situated in Charlottesville (population 6,449) and Richmond (population 85,050) The clinical facilities in Richmond are good Board and room can be obtained for $18 a month and upward, in Charlottesville and from $12 to $20 a month in Richmond

Charlottesville

University of Virginia Department of Medicine.—This school was organized in 1827 and has a faculty of 21 A free dispensary and the new four story hospital—an addition to which at a cost of $3,600 will be complete by Jan 1 1905 —furnish clinical facilities The requirements for admission are those of the Association of American Medical Colleges The course is four years of nine months each Fees First year $110 second $100 third, $80, and $60 for the fourth year Total enrolment for 1903 4 was 164 graduates 31 The eightieth session opens Sept 15 1904 and closes June 15 1905

Richmond.

Medical College of Virginia —This school was organized in 1838 as the Medical Department of Hampden Sidney College and in 1854 the present name was assumed The faculty is made up of 17 professors and 26 lecturers instructors etc a total of 43 Clinical material is furnished by the Memorial Hospital and the City Free Dispensary an outside obstetric department also furnishes opportunities for clinical work The magnificent new Memorial Hospital opened July 1903 is under the exclusive control of this college for clinical purposes The State Penitentiary City Almshouse and other public charities and asylums of the city also afford opportunities for clinical work This school is a member of the Southern Medical College Association The buildings are large and contain well equipped laboratories and amphitheaters The course embraces four years of nearly eight months each The fees are $85 for each year with an additional graduation fee of $30 The Dean is Dr Christopher Tompkins Total registration for 1903-4 was 219 graduates 41 The next session begins Sept. 27, 1904 and will end May 16 1905

University College of Medicine —This school was organized in 1893 and has a faculty of 19 professors 34 lecturers assistants, etc a total of 53 Good clinical facilities are furnished by Virginia Hospital with a maternity department and annex, which was built especially for the purpose of affording bedside instruction and is owned and operated by the college Richmond Eye, Ear and Throat Infirmary containing 34 beds the City Hospital City Jail State Penitentiary and a college dispensary Matriculation is in accord with the rules of the Association of American Medical Colleges and of the Southern Medical College Association to both of which this college belongs The laboratory and lecture-room space and equipment are ample, and some of the instructors devote their entire time to the laboratories The school lays especial importance on the careful instruction and guidance of each student The curriculum covers four years of thirty three weeks each The total fees are $85 for each year The President is Dr J Allison Hodges the Dean is Dr Landon B Edwards, Richmond Total enrolment for 1903 4 was 188 graduates 25 The next session begins Sept 27 1904 and ends May 17, 1905

WEST VIRGINIA

West Virginia, population 958,800, has one medical college, the Medical Department of the West Virginia University, located at Morgantown, a city with 2,100 inhabitants This school does not grant degrees, but prepares students in the first two years

Morgantown.

West Virginia University Medical Department —This school was organized one year ago and gives only the first two years of the medical course. Each college term extends over nine months The faculty consists of 6 professors and 2 assistants 8 in all The school is a member of the Association of American Medical Colleges. Dr J M. Simpson is the Dean and Dr A J Collett the Secretary Total registration in 1903-4 was 23 Next session begins Sept. 19 1904 and closes June 15 1905

WISCONSIN

Wisconsin, population 2,069,042, has two medical colleges, the Milwaukee Medical College and Wisconsin College of Physicians and Surgeons They are both situated in Milwaukee, a city of 300,000 people Clinical facilities are furnished them in common by the County Hospital, with 300 beds, and the Milwaukee Hospital for the Insane Board and lodging can be had for from $3 to $5 a week

Milwaukee

Milwaukee Medical College.—This school was organized in 1893 and has a faculty of 33 professors and 26 lecturers instructors etc a total of 59 Good clinical material is furnished by Trinity and the County hospitals Milwaukee Hospital for the Insane and a college dispensary This school is a member of the Association of American Medical Colleges. Ample laboratory and amphitheater facilities are afforded The course covers four years of eight months each The total fees are $125 each for the first three years and $135 for the fourth year The President is Dr William H Earles Total number of students for 1903 4 was 148 graduates 29 The eleventh session begins Sept 15 1904 and will close about May 22 1905

Wisconsin College of Physicians and Surgeons —This college was organized in 1893 and has a faculty composed of 21 professors and 29 associates assistants etc. a total of 50 St. Joseph s Hospital containing 150 beds the college dispensary the Milwaukee County Hospital and the Hospital for the Insane supply facilities for clinical study The school is a member of the Association of American Medical Colleges. The laboratories and lecture rooms are well equipped The curriculum includes four years of eight months each Fees Matriculation paid once $5 general ticket, $100, for the use of the microscope a fee of $2 is charged for each course The Secretary is Dr W H Washburn Total enrolment for 1903 4 was 86 graduates 29 The next session begins Sept 20 1904 and ends May 18, 1905

CANADA

The Dominion of Canada, with a population of 5,335,055 (1900) distributed through seven provinces and the Northwest territories, an area which reaches from the Atlantic to the Pacific, contains only 9 medical colleges Of these, 4 are situated in Ontario, 4 in the province of Quebec, 2 in Nova Scotia and one in Manitoba The distinction between university and college in Canada is definite, namely, the latter is a teaching body only and has no right to grant a degree

London, Ontario

Medical Department of Western University —This school matriculates students in accordance with the requirements of the Provincial Council and has a course of four years Victoria Hospital and St Joseph s Hospital supply the clinical advantages The fees are about $90 per year and $25 extra for graduation with $5 for each examination each year This school has over 100 students and from 10 to 20 graduates annually The next session runs from September to May

Kingston, Ontario

Queen's University —This school had 216 students registered in its medical department during 1903 4 and graduated 42 The faculty numbers 25

Toronto, Ontario

University of Toronto Medical Faculty —All the lectures and demonstrations are given in the laboratories and lecture rooms of the University, more than two thirds of the instruction in the third and fourth years is given in the wards and in the pathologic and clinical laboratories A fifth year is now required by the Ontario Medical Council The faculty numbers 88 Clinical instruction is given in the Toronto General Hospital Mercer Eye and Ear Infirmary Burnside Lying In Hospital Hospital for Sick Children and St. Michael s Hospital Before commencing students who propose to practice in the Province of Ontario must satisfy as to qualifications the College of Physicians and Surgeons of Ontario (Provincial Board) but those who desire the degree of the university must obtain junior matriculation standing prior to admission to the second examination Fees are Registration (payable once) $5 each of the first four years $100 fifth year $50 for the degree M B and M.D each $20 Number of students registered last session, 721 graduates 90 The next session will commence Oct 1 1904 Trinity Medical College of Toronto which has been in affiliation was amalgamated with the university in 1903

Ontario Medical College for Women —This college is not empowered to grant degrees but it qualifies students fully to take the examination in any university The faculty numbers 35 The fee for each year is $110 exclusive of hospital and university fees The number of undergraduates 1903 4 was 31 graduates 4 Twenty first session will open Oct 1 1904 and continue for eight months

Montreal, Quebec

McGill University, Faculty of Medicine —This college has a course of four years of nine months each The faculty numbers 24 professors and 66 assistants total 90 The total fees for the course are $500 Clinical instruction is given in the Montreal General Hospital Royal Victoria Hospital and Montreal Maternity Hospital Students except university graduates in arts must pass the medical matriculation of this university or that of one of the provincial medical boards Students registered during session 1903 4 415 graduates in June 1904 86 The seventy third session will commence Sept 20 1904

University of Bishop s College Faculty of Medicine —The course leading to the degree of C M M D extends over four years of nine months each The annual fees are $100 which include all practical classes and material for the same Students must on entering the study of medicine pass the college matriculation examination or if the license for the Province of Quebec is desired that of the College of Physicians and Surgeons of that Province Special facilities are offered for the practical teaching of obstetrics and undergraduates are obliged to take entire charge of several accouchements before being allowed to take the final examination Other clinical facilities are offered in the Montreal General Hospital, the Royal Victoria Hospital the Western Hospital the Hotel Dieu and the Woman s Hospital During the last session the students numbered 70 graduates 10 The next session will open Sept 15 1904

Quebec, P Q

University Laval Faculte de Medicine —This is the Quebec branch of Laval University medical faculty The course consists of four years The fees for the entire course are from $200 to $300 according to preliminary qualifications The matriculants are about 100 annually and the graduates about 20

Halifax, Nova Scotia

Faculty of Medicine of Dalhousie University —The course consists of four years of eight months each and leads to the final M.D and C M examination Prospective students must pass the preliminary examination of the Provincial Medical Board a university examination or a recognized equivalent During last session (1903 4) there were 58 students of whom 17 graduated The faculty numbers 23 and the next session is from September to April (inclusive)

Winnipeg, Manitoba

Manitoba Medical College —This is in affiliation with the University of Manitoba and has a faculty of 21 Winnipeg General Hospital and St Boniface Hospital supply clinical material The fees are $400 for the course of four years There were 108 students in 1903 4, and 15 graduates

---

THE ASSOCIATION OF AMERICAN MEDICAL COLLEGES

The requirements for admission to be maintained by colleges belonging to this Association are as follows

Section 1 —Each college holding membership in this Association shall require of each student, before admission to its course of study, an examination, the minimum of which shall be as follows

1 In English, a composition on some subject of general interest This composition must be written by the student at the time of the examination, and should contain at least 200 words It should be criticised in relation to thought, construction, punctuation, spelling, and handwriting

2 In Arithmetic, such questions as will show a thorough knowledge of common and decimal fractions, compound numbers, and ratio and proportion

3 In Algebra, such questions as will bring out the student's knowledge of the fundamental operations, factoring, and simple quadratic equations

4 In Physics, such questions as will discover the student's understanding of the elements of mechanics, hydrostatics, hydraulics, optics, and acoustics

5 In Latin, an examination on such elementary work as the student may offer, showing a familiarity usually attained by one year of study, for example, the reading of the first 15 chapters of Cæsar's Commentaries, and the translation into Latin of easy English sentences involving the same vocabulary

Sec 2 —In place of this examination, or any part of it, colleges, members of this Association, are at liberty to recognize the official certificates of reputable literary and scientific colleges, academies, high schools, and normal schools, and also the medical student's certificate issued by any state examining board covering the work of the foregoing entrance examination

Sec 3 —Colleges, members of this Association, may allow students who fail in one or more branches in this entrance examination the privilege of entering the first year course, but such students shall not be allowed to begin the second course until the entrance requirements are satisfied

Sec 4 —Colleges, members of this Assocoiation, are free to honor official credentials issued by medical colleges of equal requirements, except in the branches of study embraced in the last year of their own curriculum

Sec 5 —Candidates for the degree of Doctor of Medicine in the year 1899 and thereafter shall have attended at least four courses of medical instruction, each course of at least six months' duration, no two courses of which shall have been in the same calendar year

Sec 6 —Colleges, members of this Association, are free to give to students who have met the entrance requirements of the Association additional credit for time on the four years' course as follows (a) To students having the A B, B S, or equivalent degree from reputable literary colleges, one year of time, (b) To graduates and students of colleges, of homeopathic or eclectic medicine, as many years as they attended those colleges, provided they have met the previous requirements of the Association and that they pass an examination in materia medica and therapeutics, (c) To graduates of reputable colleges of dentistry, pharmacy, and veterinary medicine, one year of time

Sec 7 —A college not giving the whole four courses of the medical curriculum, and not graduating students, but otherwise eligible, may be admitted to membership

At the last meeting of this Association new regulations were adopted After July 1, 1905, matriculants must have a diploma from a four year high school or an equivalent education Full particulars were given in The Journal, July 25, page 274

The following colleges are members

Egypt June 18 25 36 cases 16 deaths

Formosa June 11 25 178 cases 129 deaths

India Calcutta, June 18-July 2 31 deaths Karachi June 26-July 3 1 case 1 death work of visitation and inspection is resumed, the preparation of the report can be proceeded with as was contemplated in the recommendation, because the information can be obtained directly from the college much more correctly and expeditiously than it is possible to obtain it from a catalogue

I have, however, begun this work and am prepared to give you the results of the little I have been able to do under the circumstances

On taking up this work I was struck by the heterogeneity and variableness of the information to be obtained from a catalogue Contradictory statements were made as often as three times in one catalogue After I had figured out the amount of time devoted to various studies in about fifty catalogues, I was forced to abandon the work because the information obtained in that way could not be utilized for any purpose Each college has its own ideas as to what should be taught and how much time should be devoted to it Some colleges devote considerable time to studies not considered worthy of a place in the curriculum by others Again, some studies are merged and are taught from one chair, so that no estimate can be made as to the time devoted to each of the studies so merged A personal communication with the teacher would be the only proper way for obtaining such information, and that requires considerable time and correspondence, as well as an outlay of much money Therefore, I have laid this portion of the work aside until some future time when conditions are more favorable for taking up a study of the curricula of medical colleges It can not be denied, however, that such a report would be of assistance to all colleges in preparing their courses of study, and in establishing a uniformity of curricula

LENGTH OF TERM

Next I took up the length of the courses, and here too, I found considerable variation Six months may mean 24 weeks or 26 weeks Seven months usually means a 28 weeks' course, but in some instances it is only a 27 weeks' course Eight months means 30, 31 or 32 weeks Nine months means anywhere from 33 to 36 weeks I made my calculation according to the calendar, including examination weeks and omitting the vacation periods A calculation based on the number of days of actual attendance would, perhaps, have been more interesting, and it certainly would have been more exact, and I shall make future calculations on this basis Then, too, the length of the senior course always is shorter than the courses of the first three years, so that the fourth year of an eight months' school would not exceed 28 weeks in length

ENTRANCE REQUIREMENTS

Considerable variation also shows itself in the matter of entrance requirements Admission by examination is possible in nearly all colleges Some colleges admit only on presentation of a high school diploma, and some specify what such a diploma should represent in work done In some instances it is rather difficult to determine just what credentials for entrance are required Some colleges give time credits for nearly all kinds of work done Others give only work credits, even to holders of baccalaureate degrees A few colleges that are parts of a university prefer to admit only such students who have completed a prescribed course in such university I have prepared a preliminary report on this, and expect to be able to present a complete report, giving the name of each college and its entrance requirements in detail It is impossible to do this in a summarized report

A number of colleges will not admit students on conditions, and that, in a large measure, may be responsible for the falling off in numbers of the medical students during the past year Of course, the raising of the entrance requirements quite generally has had much to do with this falling off

It is almost impossible to obtain a correct list of the medical colleges in this country I believe that at present I have a list that is more nearly correct than any other My information has been obtained from any and varied sources, but because of the constant formation of new colleges it is quite a task to keep the list correct

I have studied all the colleges in this country—those that are members of this Association and those that are not As a result of this study, I present the following summarized report

There are at present in the United States, including the Philippine Islands, 128 regular schools, 10 homeopathic, 10 eclectic, 3 physiomedical, and 1 nondescript, a total of 161 Of this number, 66 of the regular schools belong to the Association and 65 are non members (Of this number, four have been received into membership since the writing of this report, and applications have been filed by two more.)

MEMBERS

Of the colleges belonging to the Association, 2 are exclusively for women, 2 for negroes, 1 has both day and evening courses, 3 have a continuous course extending over twelve months and divided into four semesters of three months each, 1 college is a member of this Association and also of the Southern Medical College Association, 7 schools confer two degrees, the baccalaureate and the medical degree, at the end of six and seven years, 37 colleges have a university connection, either actual or in affiliation

AS TO THE LENGTH OF THE TERM

Four years of six months each, 6 colleges, four years of seven months each, 19 colleges, four years of seven and a half months each, 2 colleges, four years of eight months each, 23 colleges, four years of eight and a half months each, 1 college four years of nine months each, 15 colleges, a total of 66

ENTRANCE REQUIREMENTS

Rules of this Association, 11, rules of state boards of medical registration, 9, high school diploma, 8, either a baccalaureate degree or a high school diploma, plus 15 units, 1, high school diploma, plus two years of college work, 2, high school diploma, plus one and one third years of college work, 1, high school diploma, plus one year of college work, 1, baccalaureate degree, plus credits in physics, chemistry, biology, Latin and a reading knowledge of French and German, 1, high school diploma, plus three years of college course, 1

This information was taken from the catalogues of the colleges, and is the minimum requirement, in lieu of which an examination may be taken

Some colleges give no advanced standing whatever for any degree, some give a time credit of one year to dentists only, others, to dentists and veterinary surgeons, a very few give credit to graduates in pharmacy Some colleges give work credits but no time credit

FEES

I have included the matter of fees in my study The fees vary from $35 00 a term to $200 00 The medical departments of universities have low fees for residents, but the same fee does not apply to non residents A very few colleges give a discount to the sons of physicians and clergymen One college offers the tuition of the third and fourth years to students who matriculate for the freshman work in October 1903 and 1904

NON-MEMBERS

Of the colleges who are not members of this Association, 1 is exclusively for women, 1 teaches all of the "pathies" and "sects" of medicine, including osteopathy, the student choosing his work, 5 are for negroes (4 are night schools), 4 teach the first two years only of the medical course, and 1, I understand, is a diploma mill, 34 have a university connection of some kind.

AS TO THE LENGTH OF THE COURSE.

Fours years of six months each, 19, four years of seven months each, 18, four years of seven and a half months each, 2, four years of eight months each 11, four years of nine months each, 4, four years of ten months each, 3 (night schools), five years of nine months each, 1 (night school), two years of nine months each, 4, no information, 2—a total of 65

ENTRANCE REQUIREMENTS

Twelve of these schools are members of the Southern Medical College Association, and exact the entrance requirements laid down by this Association Seven other schools abide by the rules of the Association of American Medical Colleges, 5 abide by the rules of the Southern Medical College Association, 19 require a high school diploma or its equivalent 1, a baccalaureate degree, plus a chemistry credit, 2, a high school diploma, plus one year of college work, 1 requires "satisfactory evidence of educational qualifications necessary for the successful prosecution of medical studies", 1, "a diploma certificate, or examination showing proficiency", 1, "a certificate showing proficiency", 1, "certificate showing possession of sufficient knowledge", 1, "preliminary examination for applicants not possessing requisite diploma or certificate"

FEES

The fees range from $30 00 to $250 00 The colored schools ask the lowest fees, and nearly all of them ask less than $50 00 per term

This work is merely a preliminary study, and the forthcoming catalogues for the session of 1904 and 1905 will vary considerably from those of the last session, so that this work will have to be revised from year to year One fact is very evident, and that is, a total lack of uniformity in the rules and regulations of all the medical colleges in this country, and the desirability of having uniformity, in some things at least

Respectfully submitted,

Fred C Zapffe, Secretary

The financial report was referred to the following Auditing Committee Drs Egbert, Kober and Steele

Committee on Medical Education

The balance of the report was accepted, and, in accordance with the suggestion contained therein with reference to the appointment of a Committee on Medical Education, the Chair later appointed as such committee the Secretary, Fred C Zapffe

Report of Judicial Council

Dr William J Means, chairman of the council, reported as follows

The Judicial Council held one regular meeting during the year, at the Wiltshire Hotel, Atlantic City N J June 6 There were present Drs W J Means, chairman F F Ingals of Chicago, T H Hawkins of Denver, Randolph Winslow of Baltimore and H B Ward of Nebraska The meeting was called to order by the chairman H. B Ward was elected secretary

The first business was a consideration of the applications for membership made in 1903, on which action was deferred pending further investigation of the standing of the college

Dallas (Texas) Medical College, withdrew its application

The application, of the University of Tennessee located at Jackson, Tenn , referred to Dr Means for investigation was taken up, and, because of insufficient facilities and lack of teaching force, was not considered eligible for membership Rejection of the application is, therefore, recommended

The application of the University of West Virginia located at Morgantown, W Va., for membership covering the first and second years only of a four years' medical course, is, on a report from Dr Dodson who investigated the college recommended

The application of the Medical Department of Wake Forest College, at Wake Forest, N C , for membership covering the first and second years only of a four years' medical course, is, on a favorable report from Dr Winslow, recommended

The application of the Medical Department of the University of Mississippi, located at Jackson, Miss , for membership was considered, and it was decided to recommend membership covering the first and second years of a medical course

The Medical Department of the University of Missouri made application to complete its membership for a full four years' course. A thorough investigation was made of the clinical facilities of the college and the members of the council believe they are sufficient to meet the requirements for a thorough medical course. The council therefore, recommends a full membership

The Medico Chirurgical College of Kansas City, Mo , made application for membership After due consideration the council recommends that the matter be laid over one year pending further investigation

COMMUNICATIONS AND ANSWERS

During the year many inquiries were received asking for a construction of rules governing admission of students, credits, etc Among the most important, we submit the following

CHARGES AGAINST BALTIMORE UNIVERSITY SCHOOL OF MEDICINE

The following charges were preferred by the Baltimore Medical College against the Baltimore University School of Medicine

Baltimore May 18 1904

William J Means A.M M.D Chairman Judicial Council of the Association of American Medical Colleges 715 North High St. Columbus Ohio

Dear Doctor —The Board of Directors of the Baltimore Medical College has directed me to lay before your Council the following complaint against the Baltimore University School of Medicine That the said Baltimore University School of Medicine received students then in attendance at the Baltimore Medical College on or about the following dates the same being other than is permitted by the rules of the Association of American Medical Colleges

Charles H Glover left the Baltimore Medical College on or about Feb. 17 1904 entered the Baltimore University School of Medicine and graduated therefrom on April 19 1904

Wm. F Giesregen left the Baltimore Medical College on or about March 1, 1904 and graduated from the Baltimore University School of Medicine April 19 1904

Frederick S Bootay left the Baltimore Medical College on or about Feb 20 1904 and graduated from the Baltimore University School of Medicine April 19 1904

H Forsythe Stapp left the Baltimore Medical College on or about March 26 1904 and graduated from the Baltimore University School of Medicine April 19 1904

Harper A Wright left the Baltimore Medical College on or about Dec 24 1903 and graduated from the Baltimore University School of Medicine April 19 1904

Harry D Duffy left the Baltimore Medical College on or about Feb 2 1904 and graduated from the Baltimore University School of Medicine on April 19 1904

Should other proof than this statement be required we will be pleased to place before your council on request documents proving the correctness of the charges herein made.

We regret to have to make this complaint against a school in our own city a member of the Association of American Medical Colleges but believing the charges to be true and in contravention of the rules of the Association of American Medical Colleges as well as inimical to the general welfare of medical education we feel it our duty to do so

Kindly acknowledge receipt hereof at the same time advising us what further action if any may be necessary on our part.

Assuring you of our cordial personal esteem, we have the honor to remain Yours very truly

David Streett M D Dean

P S —On April 20 our Dr Samuel T Earle informed Dr R. Winslow, the resident member of your council of this matter and I presume that he has already notified you of it D S

A copy was furnished the Baltimore University School of Medicine May 21 The following answer was received May 30

Baltimore May 30 1904

Dr W J Means Chm Jud. Coun. Association American Medical Colleges No 715 N High St. Columbus Ohio

My Dear Doctor Means —I am in receipt of your favor of the 21st and in reply our faculty is more than surprised to hear that the directors of the Baltimore Medical College should have preferred any charges against the Baltimore University School of Medicine and the faculty at a meeting held Friday evening May 27 1904 has instructed me to say that each and every one of the students mentioned in your letter that is Messrs Charles H Glover William E Geisregen Frederick S Bootay H F Stapp H A. Wright and Harry F Duffy matriculated in the Baltimore University School of Medicine in October and were students at our College during the session and if they were in attendance at an other college at the same time our faculty was not aware of it.

We have no desire to do anything that would conflict with the constitution or by laws of the Association of American Medical Colleges in any way shape or form whatever and we do all we can to uphold and support the Association We have done nothing to conflict with Section 4 Article 3 of the Constitution we only honor official credentials of recognized medical colleges and under no circumstances do we allow *any member of the senior class to graduate at our institution* unless he takes all of the branches embraced in our senior year

It is our custom when a student applies to us for matriculation and shows us his credentials for his past years we never think of such a thing as asking him whether he is in attendance at any other medical college at that time

Trusting this will be satisfactory and assuring you of our earnest desire not to do anything that will conflict with your body, I beg to remain Very respectfully yours

H H Biedler Dean
Baltimore University School of Medicine.

Due notice was given both colleges to prepare their evidence for presentation to the council June 6, at Atlantic City

Dr Streett, Dean of the Baltimore Medical College, submitted evidence, properly attested, from the records of the college and teachers in support of the charges

Dr Biedler, Dean of the Baltimore University School of Medicine, denied the charges in a general way, but furnished no documentary evidence to support his statement

After due consideration of the testimony the council adopted the following

Resolved, The testimony presented by the officers of the Baltimore Medical College clearly established the fact that Chas H Glover, Wm E Giesregen, Frederick S Bootay, H Forsythe Stapp, Harper A Wright and Harry E Duffy were regularly matriculated students in said college, and continued in attendance during the time stated in specifications, and the statement of the dean of the Baltimore University School of Medicine that said students were matriculated in his college in the month of October, and were in attendance during the session, unsupported by attested evidence from records of the college and teachers, is not a sufficient refutation

Therefore, inasmuch as the charges are clearly in contravention to the rule of the association, and the requirements for graduation set forth in the college announcement, the council recommends that the Baltimore University School of Medicine be suspended from membership until satisfactory evidence is furnished from the class records and teachers of the college properly attested, sustaining the contention that said students were in attendance during their senior year

The members of the council wish to express to the officers of the association and the members thereof, their appreciation of the many kindly courtesies shown them Respectfully,

W J Means, E. F Ingals, T H. Hawkins, Randolph Winslow, H. B Ward

On motion the report was accepted.

(To be continued)

Therapeutics.

Hay Fever

Parsons, in the *Med Record* for July 16, 1904, discusses the treatment of this condition under the following three heads 1 Constitutional 2 Local 3 Treatment of the exacerbation

1 On account of the frequent occurrence of the disease in those persons with a neurotic temperament, the treatment should be directed toward building up the tone of the nervous system For this he recommends (a) The daily cold plunge, to be taken immediately on rising, or for those not robust, cold sponging of the neck and chest The bath should be begun several weeks before the usual time for the hay fever to make its appearance (b) The mode of life, diet, and exercise should be regulated (c) Wear suitable clothing and use especial care to prevent cooling off too suddenly after perspiring Avoid unnecessary exposure to drafts (d) The sleeping room should be ventilated (e) Tonics, such as strychnin, arsenic and phosphorus, are indicated 2 The nasal cavities should be examined, preferably two months before the hay fever season If any chronic inflammatory condition be found it should be relieved, if any obstruction to the nasal passages is present it should be removed All sensitive points should be touched with a caustic, such as a solution of nitrate of silver This plan of treatment may need to be renewed at the same period for two or three years before marked improvement in the severe cases can be expected 3 Treatment of the exacerbation Locally the author suggests some spray of a mild alkalin solution, followed by adrenalin solution as a spray in the proportion of 1 to 5,000 in normal salt solution The strength may be increased as found necessary It is best to follow this with some bland oily spray

For the general treatment of the exacerbation the author refers to the strong plea made by other authorities for the so called uric acid theory in the production of hay fever and the recommendations for the active treatment of this diathesis six weeks or two months before the expected onset of the exacerbation He suggests the administration of aromatic sulphuric acid, or phosphoric acid, for a time, followed by small doses of salicylate of sodium, three grains three times a day, and cutting off the acid producing drinks such as beer, wine, cider, lemonade, etc Avoid meat, strawberries coffee, tea meat extracts, vinegar, sour pickles, preserves, sugar, potatoes and other starchy foods Ham and bacon may be allowed The diet should consist principally of cereals, eggs, fish, fresh fruit, vegetables, milk and cocoa Water should be drunk freely

For internal medicinal treatment the author recommends the saccharated extract of the dried suprarenal gland, in doses of two grains, three times a day, beginning about two weeks before the attack of hay fever usually occurs, given with a view to retarding and mitigating the attack so far as possible

Camphor will often give temporary relief in hay fever, administered five drops every fifteen minutes for the first hour and repeated at longer intervals as required

COLD APPLICATIONS

Aside from the medicinal measures relief may be obtained from the use of a cold spinal douche, for from fifteen to thirty seconds, at a pressure of twenty to thirty pounds to the square inch, at a temperature of 60 degrees Patients soon become used to the douche if properly administered and followed by a brisk rub If an apparatus for the douche is not at hand, water from a pail should be dashed over the patient's back, the operator standing at a distance

CLIMATE

Change of climate benefits a large number of *patients*, a sojourn among the mountains benefits some, others obtain most relief at the sea shore especially from the surf bathing The surf bathing acts as a general stimulant and locally, by the force with which it enters the nostrils, to induce contraction of the capillaries and dilated veins Patients should not remain in the water long enough to chill The associated asthma and bronchitis may require special treatment The author advises against the use of opium or cocain in any form Patients should be advised against the use of tobacco and alcoholic stimulants during the exacerbation They should be further cautioned not to ride in the dust when that is known to bring on an attack

The following is recommended as a bland oily and sedative spray, to be used after the adrenalin solution

℞	Acidi carbolici		
	Mentholi, āā	gr i	06
	Camphoræ	gr v	30
	Liq albolin	℥i 30	

M Sig Use locally as a spray for the nose

Medicolegal.

Validity of Medical Practice Act—Association of American Medical Colleges Standard—The Supreme Court of California says, *ex parte* Gerino, where a rehearing has been denied, that the act of Feb 27, 1901, for the regulation of the practice of medicine and surgery, provides, with respect to the membership of the board of examiners, that "five members thereof shall be elected by the Medical Society of the State of California, two members thereof by the California State Homeopathic Medical Society, and two members thereof by the Eclectic Medical Society of the State of California" The power of the state to constitute such a board, and to impose restrictions on the right to practice medicine, to be enforced by the board, rests entirely on the theory that such regulations are for the general welfare, and specifically to protect people from the arts of quacks and pretenders and from the mistakes of incapable practitioners The societies named, by receiving this power of appointment, are constituted agencies of the state to perform a part of the duty pertaining to the sovereign power of the state, and they are not, in that respect, the recipients of private rights or privileges It may be true that in making these appointments each medical society will choose persons who believe in the school of medicine of which its members are composed This, however, does not render the law unconstitutional The board, when appointed, must act equally for the benefit of all applicants, and impartially with respect to each, regardless of the school of medicine to which they belong Moreover, even if method provided in the law for the appointment of the members was invalid, and other provisions of the law would stand unaffected There would then be a legal office established, without any specific provision for the appointment of any person to fill it, and the vacancy thus existing could be filled by appointment of the governor But, as it would be a legal office, it could be filled by a de facto officer, and in that case the validity of his appointment and his right to hold the office could not be questioned in a proceeding in habeas corpus Nor does the court think the act rendered unconstitutional by the provision that the applicant for examination must produce a diploma issued by some legally chartered medical school, the requirements of which "shall have been, at the time of granting of such diploma, in no particular less than those prescribed by the Association of American Medical Colleges for that year" It says that the law on this point is not to be construed so as to require these colleges to have the identical course of study and other requirements prescribed by the association The standard of scholarship required is that it shall be equal to the standard required by the association It need not be the same course of study, nor the study of the same text books, nor the attendance for the same length of time, but it must be such as requires of the student a degree of proficiency in the studies necessary to prepare him for practice equal to that which would ordinarily be produced by the requirements prescribed by the association Whether or not the Association of American Medical Colleges is composed of those only which teach the allopathic branch of that profession, the court can not say, but, admitting it to be so it can not say that there is in this provision of the law, thus understood, an arbitrary or unjust discrimination against other schools Surely they would not claim the right to have their adherents admitted to practice the profession on a less degree of proficiency in the preparatory studies than is required of those in the regular school It being proper for the legislature to demand some standard of efficiency, the court thinks it equally within its power to declare that it shall be the same as that prescribed from time to time by an association composed of colleges devoted to the work of preparing persons for the profession It says that evidently the standard of proficiency in scholarship as a preparation, and the particular studies necessary to secure a fair preparation, must change as the discoveries in natural science open new fields of investigation, and suggest or reveal new curative agencies The legislature can not successfully prescribe in advance a standard to meet these new and changing conditions Lastly, the court says that it was not necessary to consider whether or not the provision for reciprocity is constitutional Conceding, but not deciding, that such provision is void, it did not affect the other provisions of the act under which the petitioner was held in custody on the charge of practicing medicine without a certificate from the state board of medical examiners

3 —*See abstract in* The Journal, *xlii, p* 1584

4 **Carcinomatous Transformation of Gastric Ulcer**—Dunham is of the opinion that cases of carcinomatous transformation of ulcer of the stomach are probably more frequent than is currently believed Treatment may be along surgical lines with a reasonable hope of prolonging life, and along medical lines in a palliative manner A most important phase of this question is the diagnosis and prophylaxis In the majority of cases the indications of ulcer continue until the malignant invasion It is rarely possible to find a tumor The chemic and microscopic findings in the stomach contents are not characteristic of cancer until late in the progress of the disease An increase in the hydrochloric acid, usually noted until very near the fatal issue, often misleads in the diagnosis In another class of cases the ulcer symptoms continue until the end, and in a third class the ulcer symptoms may have subsided for months, or perhaps years, and a recurrence of digestive difficulties seems to indicate a return of the ulcer, but in reality they are due to the beginning of the malignant growth Having established the presence of ulcer, the physician should impress on the patient the gravity of his case He should insist on the importance of appropriate treatment, such as rest in bed, with rectal alimentation, followed by milk diet over a period of perhaps four weeks Under such a course of treatment the symptoms may become more marked The patient may have paroxysms of pain three or four times a day after taking food, and under such circumstances, with the stomach contents showing increased acidity, we may be fairly certain that the diagnosis is canceration of the ulcer Speaking of prophylaxis, Dunham says the proper treatment medically of simple ulcer in its first manifestations is a preventive measure which physicians should enforce rigidly Gastro enterostomy by a skillful surgeon should be employed in intractable chronic ulcer to prevent cancer development A recurrence of digestive disturbances after a history of ulcer with apparent recovery should be treated at once Surgical interference is successful only when resorted to early, in cases of development of cancer on ulcer

13 Reflections on the Financial Status of the Medical Career Nathaniel G Price

9 **Riggs' Disease.**—Souwers emphasizes the importance to the practitioner of knowing more about the treatment of Riggs' disease *The family history is as important as the patient s personal history and should receive proper attention if any treatment is needed* Locally, the mouth should be cleansed with hydrogen peroxid, dilute aromatic sulphuric acid, sodium carbonate and borax The mouth is then cleansed thoroughly with water and dried, after which sulphate of quinin is dusted along the seat of the disease and lightly packed between the teeth. The patient should use a mouth wash two or three times daily, at bedtime, or other convenient period, he should rinse the mouth with milk of magnesia or a solution of magnesia, the portion of the drug precipitated *or adhering to the teeth, etc , not being removed by subsequent* washing Mouth washes containing tincture of myrrh are not advisable, because myrrh is precipitated by contact with the watery secretions of the mouth, and at times finds lodgment between the gums and the necks of the teeth, thus acting as a foreign irritating body As an aid in the relief of the gum congestion, a 1 to 1,000 solution of adrenalin acts nicely, particularly in the declining stage of the inflammation In those cases in which the teeth are sensitive to temperature changes, relief may be obtained by adding a few drops of phosphoric acid to oxid of zinc and applying a thin layer of the mixture to the painful area A coat of sandarac varnish will serve as a temporary expedient This treatment, if carried out carefully, always gives the desired result

18 Intrahepatic Cholelithiasis (To be continued) Edwin Beer
19 Value of a Knowledge of Abnormal Mobility of the Iris as an Aid in Diagnosing Diseases of the Nervous System. D Kerfoot Shute.

14 **Eyestrain and the Psychoses**—Dana says that alienists do not recognize eyestrain, even as a contributing cause He has seen a few cases of eyestrain with apparent bad results mentally, in students It seemed as if the eyestrain really led to a kind of exhaustion psychosis—a mental confusion—so that they could no longer read or study, or remember This condition was accompanied by apathy and depression and lack of general interest The eyes showed refractive errors and secondary muscular strain Recovery came very quickly in most cases after rest and proper glasses He believes it wise to have the eyes of psychopathic children examined carefully After sixteen years of watching he has found hardly any cases in which eyestrain is an important and direct factor in establishing even a minor psychosis, though it modifies its symptoms and secondarily adds to the disturbance The visual function is largely automatic and spinal, and when the mind is a good mind, the visual machinery *does not* overthrow or directly and seriously affect it When the mind is unstable or the body weakened cerebral eyestrain plays its part and when the mind is unstable and the visual machinery is very poor, even spinal and migraine eyestrain may do some harm Dana suggests that "glassing" has become something

of a minor psychosis He does not think that our mental balance and nervous wellbeing are so entirely at the mercy of slight defects in an organ that has been perfected by millenniums of use and misuse

16 Eyestrain and Motor Disturbances of the Nervous System—The relation of diseases of the eyes to functional nervous disorders characterized by motor phenomena is discussed by Sachs He is convinced that not a single case can be cited in which the cure of a genuine epilepsy followed the relief of any one of the many "phorias" with which oculists are pleased to puzzle us The evidence furnished from time to time by advocates of this special doctrine is wholly untrustworthy What is true of epilepsy applies also to the relation of eyestrain and other ocular conditions to chorea minor The idea that it might be due to some slight lack of adjustment in the ocular apparatus is too absurd to be considered even for an instant In cases of so called "habit chorea" it is well to have the patient examined carefully for his ocular as well as for his nasal condition, and any existing defect, however slight, remedied It is these cases of habit chorea, and not cases of chorea minor that are relieved by such treatment as a competent oculist may suggest A careful distinction must be drawn between these two diseases The relationship between ocular affections and epilepsy, chorea and convulsive tic may be a close one in the minds of same "faddists," but it must remain a very remote one in the minds of those who have no special axes to grind and no particular therapeutic territory to exploit

21 *A Meteorological Study of the Winter of 1903 4 Carroll E Edson
22 Implantations of Silver Filigree for Cure of Large Ventral Hernia Report of Two Cases H B Perry

21 A Meteorologic Study—Some of the meteorologic data of the winter of 1903 04, as prevailing in various parts of the country, teach a lesson of therapeutic value Edson undertook this work, selecting for study only the period of winter from Nov 1, 1903, to April 1, 1904—a period of five months or 152 days, and took the following cities Boston, New York, Philadelphia, Buffalo, Chicago and Denver The article contains a number of tables showing the mean temperatures, the mean maximum and mean minimum temperatures, the average daily excess or deficiency of temperature over mean of 33 years, number of days with maximum temperature 32 F or lower, mean relative humidity, sunshine, number of cloudy, partly cloudy and clear days, precipitation in inches, and wind He says that climate is not a thing in itself, it is only the conditions of sun and rain and heat and cold and wind prevailing in any place It is not a treatment for anything, but in a disease in which our weapons are discipline, food and outdoor life, a study of meteorologic conditions will enable us to place the patient where he can obtain the best opportunity for living that outdoor life most constantly and most comfortably All weather is not the same all fresh air is not equally good, but a location like that of Denver offers, by the conditions of its climate, its lack of storm, its absence of cloud, its warmer sunshine, definite advantages for the outdoor life so essential to the welfare of the tubercular individual

32 *The Present Status of Streptococcus and Tetanus Antitoxin Injections Victor C Vaughan
33 What Light Does Our Recent Knowledge of Tetanus Throw on Other Muscle and Nerve Affections David Inglis

32 Streptococcus and Tetanus Antitoxin—The present status of streptococcus and tetanus antitoxin injections is discussed by Vaughan, and he reviews the work done in this field by Marmorek, Moser, Tavel and other investigators, both in the laboratory and the clinic Many of these streptococcus sera are practically valueless against either weak or virulent cultures of the organism The results obtained by various clinicians have been extremely variable, and while one man strongly indorses a particular serum, another just as strongly and unequivocally condemns it The results obtained from the use of this serum are so variable as to cast considerable doubt and uncertainty over its efficacy in the treatment of streptococcus infections It is evident that our knowledge of the streptococcus toxin is deficient, and before a satisfactory antistreptococcic serum can be prepared we must be able to prepare a soluble streptococcus toxin The various sera now on sale are all made very carefully and with the best of intent Each investigator has prepared what he believes to be the only true antitoxin, but they are all alike in their inefficacy There is at present no satisfactory method of standardizing antitetanic serum, and we are quite ignorant of the value of any preparation we are employing There is, however, apparently no danger of using too much, as it has been shown that antitetanic serum is harmless Its prophylactic value has been demonstrated repeatedly, and Vaughan recommends that prophylactic doses be given whenever the physician is called on to dress a wound which in his opinion might be infected with tetanus bacilli, and that this injection be repeated on the third, fifth and seventh days after the infliction of the injury

8 Fatal Case of Cyanosis with Enlarged Spleen Theodore Fisher

4 Use and Abuse of Midwifery Forceps—This subject is discussed fully by Kynoch, who believes that the forceps are used too often by men without the necessary experience in their use, and that the mortality is thereby much higher than is necessary This statement is borne out by the lower mortality rate in hospital practice than in private practice It has not yet been proved that by a frequent application of the forceps a very large saving of fetal life is obtained, but the figures at our disposal show at least a slight saving, with equally good results for the mother In the hands of a skillful operator, the condition being satisfactory for the application of the forceps, a moderately frequent use of the instrument is to be recommended Too little knowledge in the technic of the application of the forceps, and over confidence in the safety of the abundant use of antiseptics, are responsible for many of the pelvic lesions following instrumental delivery The abuse of the forceps will disappear to a great extent when medical students can obtain a sound practical training in obstetrics before they can present themselves for graduation, as is the case in the German universities Although the student may not acquire any great degree of skill or dexterity during a brief residence in a maternity hospital, yet he would learn such important details as the position of the child's head and methods of pelvimetry which would prevent one frequent abuse of the forceps, viz, in contracted pelvis

22 **Intra-Tracheal Injections in Treatment of Tuberculosis.**—Mendel reports that fully half of 100 patients in various stages of tuberculosis were remarkably improved with intratracheal injections of 6 to 9 c c of eucalyptol in an oil vehicle The technic is so simple that no special experience or skill is required and the patients all submitted willingly to the injections

24 **Hygiene Culture, Application of Hygiene to Pedagogics**—This communication was read at the meeting of the Académie on May 31, the first time in its history that a woman was given the privilege of the floor Mme. Macaigne applies the term "hygiene culture" to the new method of pedagogics which she advocates Its principle is that the child from the first should be taught that the aim of all human culture is to be useful to others, and that the foundation for this culture is the development of the two principal faculties of the human being, goodness, which impels us to wish well to our neighbor, and intelligence, which teaches us how to be useful to him History, literature, philosophy, should all be taught on an entirely different basis from that at present employed, the evolution of peoples toward progress and goodness should be the points insisted on The main idea throughout the entire education of the child and youth should be that his studies are for the purpose of perfecting and augmenting his usefulness to the world at large Mme Macaigne has made an attempt to carry out some of her ideas in several of the Paris primary schools during the last two years, with gratifying results She insists that the true rôle of the physician is to form a new science of living, which will result in a rational cultivation of the human being as we cultivate plants to derive the finest fruits from them No living creature, she says, receives such unsystematic and capricious, whimsical care as the human being The cultivation of the child, both in respect to its physical functions and the development of its mind, is not based on rational laws to produce the best results for the individual and for society We need a science of living, and it is to medicine, which possesses in hygiene the rules of healthy living that the world looks to guide it toward this science

26 **Glandular-Pulmonary Tuberculosis in the School Children of Paris**—Grancher, assisted by a dozen of his present or former pupils, has been making a careful examination of all the school children in a certain Paris ward. They found that out of 896 children 141 were affected with latent but unmistakable ganglio-pulmonary tuberculosis. This is a proportion of 14 per cent of 438 boys, and 17 per cent of 458 girls The mere "suspects" are not included in these figures If they were, the figure 141 might possibly have to be doubled or trebled Application was made to the authorities and cod liver oil and meat powder were supplied for some of the affected children, while others were transferred to a children's sanatorium Grancher makes an earnest appeal that schools should be established in the country for these latent tuberculous cases, where the children can grow up healthy in country air The total number in the schools of Paris must be in the neighborhood of 20,000 to 25,000, judging from the proportions already ascertained If boarding schools in the country are an unattainable ideal for these city children, he suggests that they might at least be boarded out in farmers' families and attend the village schools [Kerley (The Journal, July 9, 1904), has recently suggested that one of the factors in the healthiness of children brought up in the country is that the articles of food are made at home The baker and the corner grocery are at too great a distance to be available—Ed]

27 **Dislocation of the Semilunar Cartilage of the Knee**—Schlatter adds 5 cases from Krönlein's clinic to those found in the literature, bringing to 62 the number of known instances of dislocation of the semilunar cartilage of the knee All but 17 were dislocations of the internal meniscus The luxation is always due to rupture of some kind, and it may

be suspected when there is sudden pain, resistance developing in the cleft in the joint and swelling of the joint capsule Contrary to von Bruns' experience, he found that the cartilage protruded more frequently during flexion while it disappeared in extension. The results were invariably fine in every case after operative intervention, although all had been long treated in vain by other measures In some rare cases, however, some trivial disturbance in the function of the joint developed in the course of years, slight atrophy of the muscle or limitation of extension

28 Leucocyte Count in Surgical Affections.—Reich's statements are based on examination of 138 cases of inflammation of cellular tissue, 24 of osteomyelitis and a large number of appendicitis and other serious inflammations in serous membranes When the leucocyte count stands at 20,000 for three or more days or constantly rises, a progressive suppuration may be assumed Diffuse peritonitis may be suspected when the leucocyte count decreases and the general condition grows worse in case of an existing intra abdominal suppuration, even when there are no other manifest clinical signs of the peritonitis His observations indicate that a high leucocyte count testifies rather against the presence of tuberculosis After trauma or operation the leucocyte count rises abruptly in the course of six to eighteen hours to a maximum of 16,000, and gradually returns to normal at latest in seventy-two to seventy eight hours He noted also this post operative, non septic leucocytosis after strumectomies, in which case it was in striking contrast to the high or constantly rising temperature curve The objection to this diagnostic measure is that several counts may be necessary for a decisive result, and this may delay the operation too long

31 Osteomyelitic Genu Recurvatum—Kisch describes 2 cases, both in 18 year old patients The epiphysis was forcibly liberated in the first case without the use of the knife, but this intervention induced fat embolism, rapidly fatal The danger of this should deter from bloodless reposition, he thinks, and advocates, instead, linear osteotomy at the point of the deformity, with extension and the covering of the cleft in the bone with the patella taken up in a flap comprising both skin and bone

32 Wolfler's Method of Treating Hernia—Hilgenreiner's communication has already been editorially mentioned in THE JOURNAL, page 1421 of the last volume The proportion of recurrences in the 828 cases operated on has been 7 3 per cent This compares favorably with the Bassini operation at Albert's clinic with 7 5 per cent recurrences The Wölfler technic is described in full It requires only twenty to twenty five — nutes and healing is complete on an average in 14 4 days Healing was by primary intention in all but 8 per cent during the last two years The advantages over the Bassini are the avoidance of complications from traction on the spermatic cord The herniotomy is generally done with local anesthesia alone

33 Retroperitoneal Displacement of the Spleen—A case is described in which serious symptoms were observed, attributed to an incarcerated wandering kidney Fixation of the spleen in its place banished all the symptoms Splenopexy, therefore, is sufficient in such cases and it is not necessary to remove the organ even in case of threatening symptoms

34 Aneurism of the Subclavian—Oberst reports a case from Kraske's clinic which brings the number on record to 188 Study of this material impels him to the conclusion that central compression is the best non operative treatment, and central ligature the most promising operative measure The results of peripheral ligation are uncertain, and extirpation is practicable only under remarkably favorable conditions Resection of the clavicle should always be done whenever necessary

36 Constriction of Limb as Aid in Changing Dressings.—The danger of hemorrhage and all inconveniences of changing the dressings on a limb are obviated by applying an elastic band to constrict the limb above the wound Isnardi has been utilizing this simple measure during the last two years, and announces that its advantages are obvious and manifold The blood pressure in the parts is reduced to zero and the blood vessels are emptied by the anemia induced. This not only prevents hemorrhage, but protects the delicate granulation tissue from injury He has used the Esmarch bandage or ordinary rubber tube, but has found a tube like that used in the Riva Rocci sphygmomanometer the best adapted for the purpose, as also for operations on a limb He applies the tube in a linen cover which can be sterilized The chief advantage of this tube is that it can be inflated and flattened out at any moment, without removing it from the limb, thus allowing the blood pressure to be shut off or restored without the trouble of removing the tube This is frequently an advantage in operating

37 Restoration of Sunken-in Nostrils—Kofmann gives illustrations of a patient to show the benefit derived by his method of paraffin prothesis supplemented by slitting the cicatricial tissue in the nostril intracutaneously, and then proceeding to progressive dilatation of the nostril with gauze tampons

38 Plastic "Wandering Flaps"—Steinthal was called on to supply a covering for a loss of substance on the right leg, involving the knee and back of the leg The patient was a girl of 5 who had been run over by a wagon The defect was too extensive to be covered by a flap from the other leg and he found it impossible to apply a pedunculated flap from the trunk in such a way as to fit it over the defect, as it was principally on the rear aspect of the limb He overcame these difficulties by taking a pedunculated flap from the left side of the trunk and inserting its free end in a gaping incision along the inner margin of the tibia in the sound leg, which was flexed and fastened against the trunk for the purpose The flap grew in the incision and its attachment to the trunk was severed the eleventh day, after which it was an easy matter to cover the defect with the transplanted flap hanging from the sound leg like an apron The flap was originally 10 by 17 cm in size, and the final healing was excellent preserving the knee region from functional disturbances The healing was delayed by the fact that the granulations of the wound had become infected, and two months elapsed before the granulations became healthy and the flap took root After this it healed rapidly and could be severed from the other leg in twelve days and sutured finally in place five days later

40 Costal Arch in Turned-Back Flap for Access to Esophagus.—A case is described and illustrated to show the peculiar advantages of surgical intervention on the lower part of the esophagus through an incision shaped like a flaring U, extending from the junction of the seventh costal cartilage with the sternum downward and up through the cartilages of the seventh to the tenth ribs at their junction with the latter, thus including the cartilaginous portion of the costal arch in the flap which was readily turned far back, freely exposing the diaphragm and allowing the esophagus to be drawn down into view Meyer is convinced that this incision would facilitate resection of the stomach or any intervention on organs in the vault of the diaphragm

STATIC FOOT ERROR

ANALYSIS OF ONE THOUSAND CASES

WILLIAM E BLODGETT, M D
BOSTON

The object of this investigation was (1) to contribute to the sum of available statistics of static foot error, (2) to draw from the cases any warrantable conclusions

STATISTICAL SUMMARIES

The cases are from the Orthopedic Out-patient Department of the Carney Hospital, Boston, through the courtesy of Dr Painter, and include only those cases of foot trouble in which the chief factor appears to be static, i e, an error of weight bearing Thus acute and chronic arthritis of the foot, paralytic, circulatory, and recent traumatic and inflammatory conditions are excluded, but those cases are included in which any of the preceding causes determined a faulty static condition which itself had become the chief factor in the foot trouble The cases are the thousand next preceding Sept 1, 1903, and cover a period of two years and four months The data are from the hospital records and from the replies of 44 and the special visits of 125 patients in response to 600 postals

TABLE 1 —SEX RELATION TO TOTAL ORTHOPEDIC CASES

	Static Foot Cases	All Orthopedic Cases in Same Period	Per cent Static Foot Cases to all Cases
Male	426	1 162	36 7 per cent
Female	574	1 290	44 5 per cent
Totals	1 000	2 452	40 8 per cent

The female cases were in moderate excess, and the percentage of female cases to all the orthopedic female cases was slightly larger than the corresponding male percentage The static foot cases were about two-fifths of the total orthopedic cases in the same period

TABLE 2 —AGE[1]

		Per cent
12 to 19 years	166	17 0
20 to 29 years	260	26 6
30 to 39 years	234	24 1
40 to 49 years	181	18 6
50 to 59 years	96	9 9
60 to 69 years	35	3 6
70 to 79 years	2	2
Total	974	100 0
Unrecorded	26	

Two-thirds of the cases were under 40 years of age The seasons of the year in order of the frequency of application during them of static foot cases, the season of greatest frequency being first, are summer, spring, winter, fall There were entered in the summer on the average nearly twice as many cases as in the fall The total attendance of all new orthopedic cases, however, shows much the same seasonal fluctuation

TABLE 3 —TIME OF YEAR.

	Static Foot Cases	Total Orthopedic Cases	Percentage Static Foot Cases to Total Orthopedic
May 1901	31	95	32 6
June 1 to Sept 1 1901	109	216	50 5
Sept. 1 to Dec 1 1901	52	144	36 1
Dec 1901 to March 1 1902	73	174	42 0
March 1 to June 1 1902	128	305	42 0
June 1 to Sept. 1 1902	129	332	38 9
Sept 1 to Dec. 1 1902	78	215	36.3
Dec. 1 1902 to March 1 1903	93	240	38 8
March 1 to June 1 1903	144	387	37 2
June 1 to Sept. 1 1903	163	438	37 2
Total	1 000	2 546[2]	

TABLE 4 —OCCUPATION

		Per cent.
Housework (wife)	176	23 6
Housework or cooking (hired)	89	12 0
Clerk	36	4.8
Mill or factory	34	4 6
Laborer	32	4 3
Railroad	28	3 8
Waiter	24	3 2
Unclassified, requiring standing, as washerwoman barber bartender, etc	147	19 7
Unclassified, not requiring standing	179	24 0
	745	100 0
Occupation unrecorded	255	

The relation of occupation to static foot error is illustrated by the following Of 14 surface car motormen with static foot error, 7 had symptoms in only the left foot (the foot supporting the body-weight, the right being used to operate bell and brake), 2 had symptoms in both feet, but worse in the left, 4 had symptoms in both feet equally, and only 1 had symptoms in the right foot only, and in this case the left was objectively the worse The weight-bearing foot, therefore, was affected alone in half the cases, whereas the free foot was affected alone in only one case, and in this case the weight-bearing foot appeared objectively the worse

ETIOLOGY

TABLE 5 —ETIOLOGY

Trauma	85
Acute rheumatism' or other arthritis including gonorrhea	88
Excessive weight (over 180 pounds) or sudden increment of weight, as at the menopause	22
Illness just preceding onset of symptoms	22
Postpartum	12
Congenital i e said to have existed since birth and presenting though at an early age a foot completely flat with scaphoid dislocation	6

The figures in Table 5 understate the absolute frequency of operation of the respective causes in the thousand cases, because often no record was made, but they may be regarded as representing the relative frequency of the causes tabulated Cases of foot error, in which the present general condition or non-static local condition appears to be the more important factor, are, as stated above, not included in the thousand cases, thus explaining the absence of present frank polyarthritis in a review of the causes of these cases Certain conditions, local and general, though perhaps not direct causes, have been noted as predisposing or contributing to the weight-bearing error and to the liability to symptoms therefrom. Local (1) Long, slender foot, (2) hallux valgus. General (1) Mild, fleeting polyarthritic symptoms, probably toxemic, (2) depression of physical vigor, without local symptoms, except in feet, as shown by soft muscles, pale skin and mucous membranes, excessive complaining without effort at self-help, and general indolence of body and mind.

---

[1] Cases under 12 years were not treated

[2] Including 94 orthopedic cases with diagnosis unknown. In figuring the percentage to total orthopedic cases in a previous table, these cases were excluded, as some of them were probably static foot cases.

The commonest direct cause was trauma. (It may be questioned whether the trauma, for instance, a sprain, was not sometimes, rather than the cause, more the result of a static error already existent.) In many cases no satisfactory cause was found.

TABLE 6.—RIGHT, LEFT, OR BOTH

		Per cent
Right only	140	14.9
Left only	152	16.2
One side only (not specified)	28	3.0
Both	618	65.9
	938	100.0
Unrecorded	62	

In about two-thirds of the cases, therefore, both feet gave symptoms, though often not beginning at the same time. In the remaining cases, the symptoms were about equally divided between the right and the left. It was not rare to find the symptomless foot used in objectively the worse position.

TABLE 7.—DURATION AT ENTRANCE

		Per cent
One month or less	105	12.7
One to 6 months	278	33.8
Six months to 2 years	251	30.8
More than 2 years	188	22.7
	822	100.0
Unrecorded	178	

In slightly less than half the cases the duration of symptoms at entrance was six months or less. The duration of symptoms, however, was often entirely disproportionate to what must have been the duration of the deformity, only a week or two of pain being not uncommonly attributed to at least a year's or two flat-foot. Moreover, as shown in several investigated cases, a patient, especially of the working class, learns to spare his feet unconsciously, and, until he suffers a decided increase of pain, due perhaps to some unusual exertion, he regards what discomfort he has as natural fatigue. It is believed, therefore, that the duration as tabulated is too short.

TABLE 8.—SYMPTOMS

		Per cent.
Pain in feet only	643	68.1
Pain in feet and above	244	25.9
Pain wholly above feet	21	2.2
Disability or deformity (practically painless)	36	3.8
	944	100.0
Unrecorded	56	

In slightly more than 95 per cent. of the cases, therefore, pain was the leading symptom, and in slightly more than two-thirds of these painful cases the pain was in the feet and ankles only. Special interrogation of 125 cases, however, would seem to show that this proportion of cases with pain wholly confined to the feet or ankles is too large. Of the 36 painless cases 19, or more than half, were under twenty years, although of the whole thousand only one-sixth were under this age.

TABLE 9.—LOCALIZATION OF PAIN IN THE FOOT

Astragalo-scaphoid articulation (and immediate vicinity)	164
Heads of metatarsals	116
Center of heel (plantar surface)	106
Sole generally	30
Between external malleolus and cuboid	24
Plantar surface of head of first metatarsal	8

The pain in the foot was often variable and diffuse so that the patient could not refer it to any exact site. The records, moreover, usually mention the "foot" or the "ankle" as the location of the pain. Table 9 gives the exact data as far as obtained. When pain was referred definitely by the same patient to two distinct spots the case was entered in the table twice.

Pain in the foot, therefore, usually diffuse or variable, when localized, was most frequently referred to the astragalo-scaphoid joint.

TABLE 10.—LOCALIZATION OF PAIN ABOVE THE ANKLE ASSOCIATED WITH PAIN IN THE FOOT

Calf (including front of tibia)	147
Knee	73
Back	32
Hip	14

When pain was definitely referred by the same patient to two parts, as the knee and the back, it is entered twice, thus making the total larger than the whole number that had pain above the ankle associated with pain in the foot.

The calf, therefore, was much the commonest place for pain above the ankle associated with pain in the foot.

LOCALIZATION OF PAIN WHOLLY ABOVE THE ANKLE

Of the 21 cases of static foot trouble without subjective foot symptoms 13, or more than half, had pain only in the knee, usually over the internal condyle, and 4 others had pain in the knee associated with pain elsewhere above the ankle. In these cases the examination of the knee was negative, except perhaps for slight hyperemia of the joint membranes. Exact figures can not be given, but in several of the cases the causal relation of the static error in the foot to the knee trouble was attested by prompt improvement of the knee following correction of the foot. The relation of static foot error to knee symptoms as seen in the clinic is commoner than the thousand cases would thus indicate, for cases of well-developed simple villous arthritis of the knee are found frequently associated with pronated or flat feet, but, although the static foot error may well have been the fundamental cause, and although part of the treatment is directed to the feet, these cases could not justly be grouped with the static foot cases, as the static foot element in them, whatever its causal importance, was no longer the chief factor.

TYPES OF STATIC FOOT ERROR

To give the exact figures compiled regarding the types of deformity affecting chiefly the longitudinal arch would imply accuracy that is unwarrantable, for the nomenclature of the records has not been always uniform, and the types themselves are not distinct. In general, however, much the commonest type, occurring oftenest in massive feet of full-grown adults, was a moderate rotation of the sub-astragaloid tarsus about an antero-posterior axis into a valgus position, together with considerable depression of the longitudinal arch during weight-bearing, but without much abduction of the forefoot, i. e., not much rotation outward of the foot anterior to the astragalus about a supero-inferior axis (patient standing). Without weight-bearing, the longitudinal arch in this type is normal or only slightly flattened, and during weight-bearing the arch is never entirely lost. The foot is relaxed and spread out. The next commonest type, occurring oftenest in slender feet, was moderate valgus, decided abduction of the forefoot, and an arch unusually high even during weight-bearing. The deformity in both these types is pronation, but with difference in the relative amounts of the three clinical components of pronation—valgus, abduction and depression of the longitudinal arch The common incidence of a general type of deformity with a general type of foot, as noted above, suggests a determining difference in the internal conformity of the types of feet, especially of the calcaneo-astragaloid facets, as alluded to by Lovett and Cotton[3] Other types observed were (1) the thoroughly flat foot, with prominence of the scaphoid, (2) flattening of the arch of relaxed feet in weight-bearing, without commensurate pronation, due to apparently direct depression, (3) pes cavus or the contracted foot, with short tendo Achillis, but no other evidence of paralysis

In nearly all the cases the anterior arch was involved to some extent, in 156 cases, notably spread and flattened, and in 116 cases, as tabulated, painful In 68 cases, the concurrence of spreading and flattening of the anterior arch, distinctive pain at the heads of the metatarsals (almost always centering at the head of the fourth metatarsal), and usually callous under the anterior arch, made the distinct diagnosis of broken anterior arch Of these cases, 41, or about three-fifths (only 2 9 per cent more than the percentage of total female static foot cases), were women, 10 (2 men and 8 women) had had the definitely characteristic, sudden attacks of excruciating matatarsalgia, relieved by removal of shoe

The degree of deformity, whatever its type, was no indication of the severity of symptoms A few of the cases complaining of pain had feet apparently normal, but were relieved by treatment of the inferred static error

TABLE 11 —CONGESTION VARICOSITY HALLUX VALGUS

Congested	65
Varicose veins	45
Hallux valgus marked (Minor grades common)	77

Of the 77 cases of marked hallux valgus, 14, or 18 2 per cent, suffered from definitely broken anterior arches, while in the 1,000 cases the percentage of broken anterior arches was only 6 8 per cent

TABLE 12 —SWELLING

		Per cent
About astragalo-scaphoid articulation	33	58 9
About external malleolus	10	17 9
About both malleoli	6	10 7
Over dorsum	4	7 1
Prolonging heel cushion forward	3	5 4

TABLE 13 —TENDERNESS

		Per cent
Center of heel	16	64 0
Over astragalo-scaphoid joint	6	24 0
Sole	2	8 0
Cushion of first metatarpo phalangeal joint	1	4 0

Tables 12 and 13 are incomplete, and represent relative, rather than absolute, frequency Swelling when diffuse, as commonly, is not included

In broken anterior arch there was usually tenderness about the head of the fourth metatarsal

The commonest place for swelling was over the astragalo scaphoid articulation, and the commonest tender point was the center of the heel

TABLE 14 —MOBILITY (IN PASSIVE MOTION)

Inversion restricted (with dorsal flexion as a rule also restricted)	130
Dorsal flexion restricted (with inversion practically normal)	45
Generally restricted	69
Increased	20
Normal	257
Unrecorded (presumably no restriction)	479
	1 000

In 88 cases, mobility, almost always in inversion, was sufficiently restricted by spasm, adhesions, or adaptive changes in tendons or bones, to require special treatment, of these cases, 58, or 65 9 per cent, were men, contrasted to the 42 6 per cent of male cases in the whole series

In about one-quarter of the cases there was notable restriction of passive motion, in one-twelfth of the cases this restriction required special treatment, restriction of motion requiring special treatment was commoner among men than among women

TREATMENT

To make the results significant, it is necessary to give an outline of the treatment used In a great majority of the cases (86 7 per cent) a steel sole plate was advised, usually at initiation of treatment, sometimes after failure of other means, or in course of treatment These plates were made as follows a plaster impression was taken in each case, the patient sitting upright and allowing the partially corrected foot (or feet) to rest on the bottom of the pan of plaster, the cast, made by filling this impression, would then be gouged out, shaved, and marked for a plate of the shape and size needed by the particular foot The plates were usually of No 18 gauge steel, spring-tempered, covered with leather on both sides The prevailing type of plate, chiefly for what has been described as the commonest type of deformity, was the square plate, supporting nearly the whole width of the sole from just anterior to the weight-bearing surface of the heel to the sesamoid bones of the great toe A posterior outside flange, to keep the foot from slipping off and a small posterior inside flange were used, but neither side as a whole was rolled up, and the scaphoid and the base of the fifth metatarsal were not inclosed For broken anterior arches, the plate was extended and raised under the heads of the middle metatarsals Much abduction would be opposed by an anterior outside flange High heel flanges and various modifications were used in needful cases Flannel bandaging and supporting adhesive strapping were employed where indicated

Local and general tonic treatment, foot exercises, right shoeing, and correct muscular standing and walking were often recommended Rigid valgus was treated by adhesive strapping in as much correction as possible followed by plate when the foot became sufficiently flexible, intractable cases were forcibly corrected by manipulation under ether, and retained overcorrected by plaster cast, followed by plate and usually Thomas sole Thomas heels, or heel and soles, were occasionally used in promising cases in substitution for plates Temporary felt pads and leather felt pads were among the measures employed The treatment thus outlined represents only the routine, and does not give account of the adjustment of the routine to the individual

ALTERATION OF PLATES

Of the 1,000 cases, 513 did not return for continued treatment, of these, at the prevailing proportion of 86 per cent, 451 must have been cases in which plates were advised, this leaves of the total 847 plate cases, 396 to form the basis of the following table If these 396 had all diligently continued to follow treatment, the number of alterations needed and made would doubtless have been increased It is probable, as will be shown later that the need for plate changes among the 451 who did not return was no less than among the 396 included in the table

TABLE 15 —ALTERATION OF PLATES

Time After Application of Plate	Under 1 mo	1 to 2 mos	2 to 6 mos	6 mos 1 year	1 to 2 years	Total
Raised	103	29	28	13	3	176
Repaired—usually broken	7	6	31	34	7	85
Adjusted—because painful	24	9	12	1	0	46
Lowered	3	4	3	2	1	13

Cases in which plates were raised more than once each case entered only once in table twice 28, three times, 6, more than three times, 5 Alterations with time not specified, not entered in table, 7

---

[3] Boston Medical and Surgical Journal Aug 4 1898

Thus, in two-fifths of the plate cases returning for after-treatment, the plates were raised, usually within a month The need for this raising, due to the patient's becoming accustomed to the plate, to plantar moulding and atrophy, and to elevation of the arch, was conspicuously shown by the relief it gave from returning symptoms A higher plate at outset would, as a rule, apparently not have been tolerated, indeed, the same plates, which, in a few weeks, unquestionably required raising, the patient at the beginning often could not wear steadily, but on account of the initial height of the plates had to become used to them gradually

About one-fifth of the plates broke during the first year of use, usually due to continuous moisture and resultant rust This breakage has recently been prevented apparently satisfactorily by galvanizing the plates with omission of the lower leather

RESULTS OF TREATMENT

Five hundred and thirteen cases of all kinds of static foot error did not return for after-treatment, and there are consequently no hospital records of the results of treatment Of these cases, however, 85 have recently been examined or heard from, after a period since initial treatment (usually plate), average 6 to 7 months, and the results subjoined will perhaps serve as a basis for estimating the results in all the deserters

"Entire relief" in the following tables means without inconvenience of any kind from feet, "relief," occasional pain in feet usually after much use, "slight relief," *pain in feet less, but present more or less all the time*, "no relief," pain as much as ever Intermediate results are expressed by the one of the above terms nearest in meaning

TABLE 16—RESULTS OF INITIAL TREATMENT

		Per cent
Entire relief	21	27 6
Relief	33	43 4
Slight relief	4	5 3
No relief	18	23 7
	76	100 0
Treatment rejected	9	

About one-quarter, therefore (if the same proportions hold for all), of the cases that did not return after the initial treatment (usually plate), were entirely relieved, and slightly less than the same number were entirely unrelieved

TABLE 17—RESULTS OF PLATE TREATMENT OF STATIC ERROR AFFECTING PRINCIPALLY THE LONGITUDINAL ARCH

	Under 1 mo	1 to 6 mos	6 mos 1 year	Over 1 year	Total	Per Cent
Entire relief	5	28	13	21	67	32 7
Relief	8	56	21	7	92	44 9
Slight relief	3	8	3	2	16	7 8
No relief	3	17	2	6	28	13 6
Worse	0	0	1	1	2	1 0
	19	109	40	37	205	100 0

Of the cases involving principally the longitudinal arch, one-third were entirely relieved by plate treatment (of course with the accessory treatment as described in the outline of treatment), with after-treatment, and only one-eighth unrelieved, in contrast to only the one-quarter entirely relieved, and the one-quarter unrelieved of the patients who received, as a rule, the same *initial treatment*, but deserted without after-treatment The importance of after-treatment is further manifested by the improvement in results with the increasing duration of treatment, thus, as shown by the table, about three-fifths of the cases under treatment more than one year were entirely unrelieved, while of the cases under treatment less than six months those *entirely relieved were only one-quarter*

TABLE 18—RESULTS OF PLATE TREATMENT OF STATIC ERROR INVOLVING PRINCIPALLY THE ANTERIOR ARCH

	Under 1 mo	1 to 6 mos	6 mos 1 year	Over 1 year	Totals	Per Cent
Entire relief	0	2	7	0	9	32 1
Relief	2	8	3	2	15	53.6
Slight relief	0	0	0	0	0	
No relief	0	0	1	3	4	14 3

Of the 10 cases with sudden, disabling metatarsalgia 5 did not return after initial treatment, and have not been found One was entirely relieved by plate for 8 months, then attacks returned, plate needed raising Two were relieved at end of a month by strapping of anterior arch and plate Of the two remaining, one continued to have attacks of undiminished severity, but less frequently, and the other was entirely unrelieved, although both had been faithfully under treatment, for ten months and one and a half years respectively

The results of treatment of cases involving principally the anterior arch were strikingly similar to those in the longitudinal arch cases one-third entirely relieved, one-twelfth unrelieved, and the rest all relieved considerably In the cases of sudden, severe metatarsalgia, the results were not so good

THOMAS SOLES AND PLATE SUBSTITUTES

The results of treatment by Thomas soles without plates—entire relief, 2, relief, 4, slight relief, 1, no relief, 3—tend to show that this treatment, even in picked cases, was less effective than plate treatment, to which several of these cases had to come Flannel bandaging and alternate hot and cold showering, or felt pad and strapping were also used, in promising cases of mild static error of the longitudinal arch, to bridge the patient over to physiological recovery, without committing him to the plate-habit In 16 such cases, only 4 were unrelieved, but later 1 came to Thomas soles and 5 came to plates

TABLE 19—ADHESIVE STRAPPING FOR RESTRICTED INVERSION

	Under 1 mo	1 to 6 mos	6 mos 1 year	Over 1 year	Totals
Entire relief or relief	3	5	1	0	9
Slight or no relief	0	3	0	0	3
Flexible	4	2	1	0	7
Still rigid	0	3	1	2	6

In three-quarters of the cases with restriction of inversion sufficient to require corrective adhesive strapping, the pain was entirely or much relieved, although the flexibility was much improved in only a half of a series of similar cases The relief of symptoms without restoration of mobility, even with the plate, usually did not continue long after the last strapping

TABLE 20—FORCIBLE CORRECTION UNDER ETHER

	1 to 6 mos	6 mos 1 year	Over 1 year
Flexibility nearly normal	3	1	0
No record of change of mobility but symptoms relieved	2	1	0
Rigid again	6	5	1

Thus, in two-thirds of the cases of forcible correction under ether, the valgus and rigidity, in spite of plaster cast, adhesive strapping and plates, returned, although in several cases forcible correction was repeated, and in one case was performed five times with unpreventable return each time of rigid valgus due to peroneal spasm In these not uncommon cases of spasm of the peroneals, resection of a short musculo-tendinous piece of the two muscles and their common sheath has recently in the clinic been giving apparently satisfactory and permanent results

REMOVAL OF PLATES CHANGE OF HABITUAL FOOT POSTURE

Among the 350 plate cases in which results are known, although a half and more had worn their plates over six months, only 15 removed their plates with relief (6) or entire relief (9) Of these 15, 5 had worn plates less than 6 months, 5, 6 months to 1 year, and 5, more than one year, the majority of these gave up plates without advice Six cases, one after three years of plate wearing, are known to have made, without advice, determined attempts to give up their plates, but were forced back to them by returning pain The unavoidable inconvenience of plates and the natural desire to be rid of them, as illustrated in these six cases, and the common return of symptoms after breakage of plates, make it improbable that any considerably larger number of the 350 plate cases than the fifteen could have discontinued their plates with comfort The 95 7 per cent of all the plate cases in which the results are known continued to wear their plates because they could not do without them After more than six months on the average, they subjectively needed plates as much as ever

To explain this continued subjective need objectively, the prevailing foot-posture in standing and walking was observed in 125 cases, nearly all of whom had steadily worn plates for averaging six to seven months, and compared with the recorded posture at entrance These comparisons could not be made accurate, because, as before noted there was no accurate method of measuring and recording the posture,[4] even if this posture had been uniform during the observation, and not shifting, requiring a composite judgment but roughly speaking it seemed unquestionably that in nearly all the cases, painful or painless, plate-wearing or cases in which plates had been successfully discarded, with the exception of the abducted-pronated feet of growing boys and girls, there had been produced by the plate-wearing no practical change in the prevailing posture of the feet when used without plates, although, as indicated by the common need for plate-raising, the sole was molded and hollowed, and the arches were apparently more easily elevated by artificial support The muscular control, also, as a rule did not appear improved

SOME REASONS AND REMEDIES FOR FAILURE TO RELIEVE

Some of the reasons for failure entirely to relieve or to maintain entire relief that have been made obvious by a review of the series in light of the results may be summarized as follows

1 Patient's failure to return for after-treatment (raising or adjustment of plate, etc) The patient regards the plate as a shoe which is to be worn unchanged until worn out

2 Patient's failure intelligently and resolutely to co-operate in achieving cure The patient expects that the plate will cure his foot in the sure, quick, lazy way in which the charlatan's specific holds forth to cure consumption

3 Remaining or returning interference with correct weight-bearing position and normal mobility of the foot (spasmodic or shortened tendons, intertarsal adhesions bony obstruction)

4 Mistake for a simple static foot trouble of a foot trouble partly static but chiefly symptomatic of some other condition (arthritic or polyarthritic, circulatory, neurological, etc)[5]

In a comparatively few of the cases, the reason or reasons for failure to relieve are obscure, and in spite of painstaking treatment diligently followed relief was not afforded In one case, for instance, thorough local and general treatment, including general institutional hydrotherapy, was followed for six months before relief began to come

These reasons for failure to relieve imply the corresponding remedies too plainly to bear mention One remedy, however, it is believed, can not easily be overemphasized the patient's intelligent, resolute co-operation Such co-operation though, especially in a hospital clinic, often hindered and sometimes prevented by the character of the patient, depends in all cases on effective instruction and encouragement, varying, of course, with the kind of patient and the kind of foot The patient should be told and shown how to stand and walk to the best mechanical advantage, by the voluntary correction of pronation and the muscular use of foot and toes Special exercise, correct shoes and foot wear, home manipulation for restriction of mobility tonic bathing, local or general, and increase of physical vigor should, in needful cases, be explained and advised These means of self-help, intelligently and resolutely used, with, or even without a plate substitute temporarily would, in a considerable number of cases it is believed, be sufficient, thus avoiding the plate habit The engaging, suggestive effect of a plate, however, more than of any plate substitute or of any other measures, is, in treatment of many cases, a factor of real importance If a plate is used, it should be explained to the patient that the plate will probably need raising or alteration, and in most cases that it is to be regarded only as a temporary crutch, in addition to the rest of the treatment, which is to be discontinued, under advice, as soon as possible For painlessness through plate wearing, although in some cases the best possibility is never perfect cure

---

PRACTICAL NOTES ON OINTMENTS, THEIR USE AND ABUSE *

L. DUNCAN BULKLEY, A M , M.D
Physician to the New York Skin and Cancer Hospital Consulting Physician to the New York Hospital
NEW YORK.

From time immemorial ointments have been employed in treating diseases of the skin, and the numerous references to them in the Bible show how highly they were esteemed One reference, namely, "Dead flies cause the ointment of the apothecary to send forth a stinking flavor," refers to an important point to be considered, that is the freshness or rancidity of ointments

While it might seem a simple and easy matter to prescribe an ointment for a diseased condition, any one who has dealt much with diseases of the skin not only often recognizes the difficulties connected therewith, but sees continually the uselessness or harm of many that have been previously prescribed for patients by others

---

[4] An effort to measure pronation by the angle between the intermalleolar diameter and the long axis of the foot proved as in the experience of Drs Lovett and Cotton unprofitable because the relation of the amount of abduction i e. increase of the angle to the amount of pronation is not constant

[5] No static foot trouble is without a cause and strictly is always symptomatic but by simple static foot trouble is meant foot trouble due more to the weight bearing error than to the greater or less complex of causes from which the weight bearing error springs. It is only the former cases of which as before stated the present series was intended to be composed.

*Read at the Fifty fifth Annual Session of the American Medical Association in the Section on Cutaneous Medicine and Surgery and approved for publication by the Executive Committee Drs H W Stelwagon J A Fordyce and H G Anthony

A practical study of the subject, therefore, may aid some in avoiding certain of the errors which continually occur in this line of therapeusis. The subject is a larger one than can properly be treated of in a single paper, and many important matters must be very briefly considered.

PATENT OINTMENTS

In regard to the innumerable patent ointments which have appeared in succession for years as cures for many or "all diseases of the skin," and some of which of late years have been so ingeniously thrust on the profession, some may have value, if rightly used in suitable cases, but their very number and variety show their relative uselessness. They may serve to relieve the physician of the effort necessary to prescribe a suitably compounded ointment, but experience proves their value to be extremely limited; indeed, they are often found injurious. Their uncertain composition, which is found to vary considerably at different times, and the doubtful testimonies of their efficacy, generally from unknown and inexperienced persons, quite excludes them from our serious consideration.

The United States Dispensatory contains formulæ for over fifty ointments for various purposes, many of which are well known and are of value, as recommended, but some are too weak and many of them are far too strong for ordinary use, unless diluted. It is, therefore, hardly safe to always rely on the directions there given in regard to the use of ointments in diseases of the skin.

There are so many items to consider in connection with this subject that it will be well to take them up in regular order under the following heads: 1, bases for ointments; 2, ingredients; 3, methods of compounding; 4, strength; 5, mode of application and removal; 6, indications and contraindications for ointments. No attempt will be made to fully cover all these topics, but practical suggestions are offered as to matters which experience has shown to be of importance.

BASES FOR OINTMENTS

The first requisite for a good ointment for the skin is that its base shall be non-irritating and of a proper consistency, and the tendency of many ointments to become rancid should never be forgotten by the physician. This will sometimes happen through the carelessness of the druggist, more often by that of patients in keeping them too long. Not infrequently an old ointment will prove irritating when one freshly and properly prepared, with the same ingredients, will prove serviceable.

Lard is a common base of very many of the ointments of the dispensatory, and to prevent its rancidity it is commonly treated with about 2 per cent. of benzoin, or originally the tincture of benzoin was added. This latter may prove irritating to the skin, and sometimes the lard is imperfectly benzoinated and will not keep.

Wax and oils also often enter as ingredients, which may likewise tend to rancidity. The petroleum products, paraffin, vaselin, albolene, etc., are also used considerably as bases, but it must be remembered that vaselin is not acceptable to every skin. Not at all infrequently an ointment made up with it will prove irritating, when the same ingredients with another base will be satisfactory.

Vaselin and albolene are often of value when it is desired to have only a lubricant, or a soft ointment to penetrate, as in the hairy scalp, but as a protective ointment it does not answer, unless materially stiffened with powder, as in the Lassar paste, or with wax, paraffin or lanolin.

Lanolin is rarely suitable as a base alone. At one time it was thought that it would be valuable as promoting absorption, when this was desired, but experiments have shown that it is far inferior to vaselin in this direction. Glycerite of starch often serves excellently as an excipient in irritable conditions, and also for general inunction after bathing, in dry conditions of the skin, but the susceptibility of some skins to glycerin must always be borne in mind, for to some it proves an irritant. Mutton tallow melted and thoroughly incorporated with enough oil, makes an excellent inunction for dry, harsh skin. Goose grease has been highly praised as an excipient, especially for parasiticides in the vegetable parasitic diseases. The newer proprietary bases, vasogen and endermol, serve good purposes and appear to be bland and unirritating.

Perhaps the most serviceable base for most ointments is cold cream, or the unguentum aquæ rosæ of the Pharmacopeia, but care must be exercised that it is well made, and that it is fresh, as it is liable to become rancid, and the water in it to evaporate. A little carbolic acid, 1 to 2 per cent., will preserve it for a considerable length of time.

A word in regard to diachylon ointment, so commonly associated with the name of Professor Hebra of Vienna. As directed now to be made, by melting together equal parts of lead plaster and olive oil, it is not as serviceable as that made after Hebra's original formula, for the oil is not decomposed in the process. Hebra advised that the ointment be made direct from the litharge, olive oil and water, the two latter in very much larger quantities and the water double that of the oil. The water and oil are boiled, with constant stirring, and the litharge sifted in and the whole stirred until a good soft ointment is made.

INGREDIENTS OF OINTMENTS

While many of the standard ointments, as those of zinc, mercury, sulphur, etc., are of more or less value used alone, undoubtedly much gain can be had by a proper and judicious combining of various ingredients to suit individual cases, although sometimes prescriptions are seen exhibiting a marvelous polypharmacy, useless if not harmful. The addition of carbolic acid, 1 or 2 per cent., is a most valuable adjuvant to many ointments, and ichthyol, 6 to 12 per cent., is also of great value as an antipruritic, as is also oil of cade. Salicylic acid is also serviceable as a promoter of the growth of healthy epithelium, and may be added to various ointments in a strength of from 3 to 6 per cent.

Many illustrations could be given of the advantage of combinations of ingredients in ointments. Perhaps the most striking is in regard to what is often known as Wilkinson's ointment for scabies, which may be further improved by the addition of tar ointment and liquid storax. It must be remembered that the ingredients of ointments must often be changed to suit individual cases, and it is not always safe to take prescriptions, of ever so high an authority, without considering well the ingredients and their suitability to the diseased condition and the particular skin under treatment.

COMPOUNDING OF OINTMENTS

The Dispensatory is very clear in its general and special directions in regard to compounding ointments, but unfortunately, these are not always strictly followed, and one occasionally meets with ointments very poorly prepared. It is well, therefore, for the physician to inspect them from time to time, to be sure that they are fresh and perfectly prepared The most common error is in having gritty particles, which are often most irritating to the surface I have seen an ointment of red oxid of mercury ordered for use on the eyelids, in which there were hard, solid particles, suggesting red pepper, stirred into the base

I have also frequently met with ointments in which there was much gritty substance, easily felt in rubbing them between the fingers All mineral ingredients should be very thoroughly triturated in a mortar, with a few drops of oil, so as to make a fine paste, which is then thoroughly incorporated with the base The more I see of practice the more I am convinced that a certain proportion of the want of success often occurring in connection with the treatment of diseases of the skin is owing to the faulty pharmaceutical prescriptions

STRENGTH OF OINTMENTS

Both in health and disease individual skins differ very greatly in their reaction to external irritants, and one should always be cautious in making a first application to a skin with which there has been no previous personal experience Irritation and harm is continually done to eruptions by too strong ointments, and it is always well to begin with a mild application, increasing the strength as indications occur Undoubtedly the reputation which oxid of zinc ointment has acquired, and also possibly some of the patented and advertised ointments, lies in their bland, non-irritating character, which may be all that is required in any particular case

One will make very little headway in treating most diseases of the skin who knows only oxid of zinc ointment, although with it alone he will probably do more good and less harm than with any other single ointment

PROPERTIES OF OINTMENTS

The strength and composition of ointments must naturally vary very greatly with the purpose for which they are employed, and this should always be kept distinctly in mind in the treatment of any cutaneous condition Ointments may be required for several very different purposes, and, according to their composition, their action may be lubricating, protective, soothing, astringent absorbent, stimulating, or antiparasitic All of them may prove healing according to the nature of the complaint and the condition of the skin These actions may be briefly considered

Lubricants—In many instances only a lubricant is wanted, and no mineral or other ingredients are required other than perhaps 1 or 2 per cent of carbolic acid Vaselin or albolene answers often very well, but a very valuable combination for general use is made as follows

R	Lanolin	℥i	30
	Boro glycerin	℥ss	15
	Unguenti aquæ rosæ	℥iii	90
M.			

An ointment of mutton tallow and olive or cod-liver oil, which can be cheaply made at home, is very serviceable in ichthyosis and in conditions where large quantities are long to be used Glycerite of starch is also very acceptable to many skins

Protective—The protective feature of an ointment is often a very important one, which will be spoken of more fully shortly when considering the mode of application of ointments

Soothing Properties—In very many diseased conditions of the skin the soothing character of an ointment is that which is most required and here it is that the ingenuity of the physician is often most severely taxed Especially is this true when the element of itching is prominent, and when one remedy after another in ointment form will fail to give relief In many of these instances some other application, in the form of a lotion or powder will be more suitable

In attempting to give relief from itching great care will often be necessary to avoid remedies which overstimulate the skin, for continually it will be seen that stronger and stronger applications are used with only irritating effect when a mild, soothing ointment will accomplish better results, especially if rightly applied Such ointments as the following will often give relief after much more powerful remedies have failed

℞	Acidi carbolici	gr v		33
	Pulv calamini prep	℈i	1	33
	Zinci oxidi	ʒss	2	
	Ung aquæ rosæ	℥i	30	
M.				
℞	Ung picis	ʒii	8	
	Zinci oxidi	ʒss	2	
	Ung aquæ rosæ	ʒvi	24	

In increasing the strength of ointments great care should be exercised and the effect carefully noted

Astringents—In certain cases more of an astringent action is required, and tannin, ergot, lead and bismuth may be added to meet different requirements

Absorbents—Again an absorbent effect is often desired in an ointment, and the preparations of iodin and mercury prove most valuable, as also tar and its various congenors

Stimulants—Stimulating ointments are also often called for, especially in more chronic conditions, and there are a large number of these which, however, must be used with caution and with a definite end in view

Many of the ointments found in current literature may be thus classed, and while in skilled hands and applied just rightly, they can be used with safety and often with advantage, in a large share of ordinary cases they will often irritate the skin unnecessarily and be worse than useless

Parasiticides—Lastly antiparasitic ointments often present considerable difficulty to those not greatly accustomed to their use, and frequently to the experienced it is a difficult matter to secure an effective ointment which is not too stimulating Especially to the scalps of children the ointments often suggested are either too weak or too irritating Chrysophanic acid, although a fairly efficient parasiticide, is being less and less used, owing to its objectionable staining of the skin, hair and clothes The iodin preparations and soluble mercurial ointments, such as the oleate and diluted citrine ointment, together with salicylic ointments afford the best results

MODE OF APPLICATION

The mode of application and removal of ointments are often very important matters, about which far too little thought is given, for these have much to do with their good or bad effect It is rare to find that specific directions have been given to patients, and yet, as it is often their first experience in this procedure, it is hardly to be expected that they will understand exactly the way to apply them in order to get the best results The usual direction is simply to apply some of the ointment morning and night and very commonly patients will diligently wash off one application before the next one is made, and not infrequently their faulty method of treating the skin will do much to counteract the benefit from the ointment used

The mode of application of an ointment must vary greatly, according to the purpose for which it is used Thus, when an ointment is used for lubricating, as in ichthyosis, xeroderma, or in a slight general eczematous state, the soft ointment should be taken on the palms and the body freely anointed, with friction, morning and night, until much of the ointment has been absorbed Also in the treatment of scabies the appropriate ointment should be rubbed in, with the palms, over all the affected parts, and even for half an hour, until it has well penetrated the furrows made by the insect, and a considerable quantity should be left on, so that the underclothing becomes pretty well saturated with it

On the other hand however, on a more or less raw, eczematous surface such a procedure would be anything but beneficial, and the ointment should be thickly spread on the woolly side of lint and firmly bound on the part with as light a gauze bandage as possible The same is true when it is applied to such a lesion as pemphigus or an ulcerating surface In this latter case, however, it is often well to spread the ointment on very thin layers of absorbent cotton, held on the hand, which may be made to fit an uneven surface, and on removal they will come off easier, without tearing the newly formed granulations This method is also peculiarly satisfactory in eczema about the anus, and in hemorrhoids, as it can be well tucked in and keeps its position

Between these two extremes there are varying degrees of active application of ointments, and patients must be instructed just how to use them or much of the benefit will be lost Thus, in parasitic diseases of the scalp, after clipping the hair very short, it is often well to apply the ointment with a stiff stencil brush, with considerable friction, working it well into the follicles, and the same mode of application is valuable in hard patches of psoriasis on all parts of the body

Again, in old patches of eczema there is often much benefit from a greater or less friction with the finger, or often with a bit of flannel with the ointment, after which the patch is covered with the same spread on the woolly side of lint and bound firmly in place In many cases of eczema or psoriasis about the hands it is almost impossible to make any progress unless the proper ointment is kept bound on the affected part all the time, night and day, for a while

In itching conditions it may be necessary to renew the applications of ointment many times daily, and in eczema of small children the direction should be to replace it as often as it is rubbed off or the dressing becomes at all deranged

In general itchy conditions, as pruritus and urticaria, it may be necessary to make applications of an antipruritic ointment many times day and night

Often one sees very poor results in the using of ointments, resulting from the coverings or dressings which are placed over them It is not at all uncommon to see a diseased surface to which ointment has been applied, covered with old linen or surgical gauze, which readily absorbs the greasy portion of the ointment very shortly, and leaves the affected portion dry, perhaps coated only with the mineral or other ingredient This is not at all conducive to the healing of the part

As has been already mentioned, the best results are obtained when the proper ointment has been spread thickly on the woolly side of surgical lint, or spread on very thin layers of absorbent cotton, and bound firmly on the part

Many errors continually occur unless careful and explicit directions are given by the physician in regard to the removal of ointments and the subsequent treatment of the diseased surface It seems to be the universal idea that such should be frequently washed, and one continually finds healing prevented by the application of soap and water, daily or oftener, when with proper use of the same ointment good results followed

Rarely, is it advisable to wash surfaces which are at all raw, and all the cleansing necessary may be accomplished by the gentlest wiping with absorbent cotton Much harm is also often done by a rough removal of ointments and dressings When the latter adhere too closely it is generally because there has been too little ointment used or an improper covering made If on removal of a dressing there is much ointment on the skin which it is desirable to remove, this can often be best accomplished by means of a dull knife, if gentle wiping with absorbent cotton is not effective

INDICATIONS AND CONTRAINDICATIONS FOR THE USE OF OINTMENTS

It is not always an easy matter to know just the exact indications for the employment of this or that kind or strength of ointment, or, for any ointment, in preference to some other kind of dressing, and disappointment will occasionally follow the best directed efforts In some acute inflammatory conditions of the skin lotions and powders suit far better than ointments of any kind while in the more chronic conditions, with dry, rough skins, ointments are, of course, called for

The exact kind and strength of ointment can be determined only after a careful study of the skin, lesions present, and their acute or chronic state or condition, and also after a full appreciation of the character of the skin of the individual under treatment

In general, a thin, delicate skin, especially in one with a light complexion and hair will bear and require much milder applications than a thick, tough skin, especially in a brunette

The single or localized patch of chronic eruption will, of course, bear and require much stronger applications than an acute or generalized eruption While the sensations of the patient will commonly determine the continuance or disuse of an ointment, and great harm is not often done by too strong applications, our efforts should undoubtedly be directed to securing an application which will be effective and accomplish the end desired, if that be at all possible

Every point in a case should, therefore, be carefully weighed and the indications and contraindications looked for and appreciated, before determination is made as to the proper ointment to apply The almost universal use of zinc ointment is largely explained by its relative harmlessness, on the principle of the Irishman's holy water, who explained that, "if it does you no good it will do you no harm" This, however, is a poor principle to go on in the treatment of diseases of the skin, which often require very active measures for their removal, and, as before remarked, he is very poorly equipped for their treatment who knows only zinc ointment.

In concluding these brief practical notes on the use and abuse of ointments, for the general physician I must utter the caution that we have been considering only one side of the great subject of the treatment of diseases of the skin, and one which is often the least important All local measures are constantly found to be ineffective unless proper and adequate internal and general treatment is adopted and earnestly and faithfully carried out

COVER-GLASS CULTURES AND THEIR POSSIBILITIES IN STUDYING EPIDERMIC FUNGI *

J FRANK WALLIS, M.D

Instructor in Dermatology Philadelphia Polyclinic Dermatologist to the Southern Dispensary Dermatologist and Radiotherapeutist to the Henry Phipps Institute

PHILADELPHIA.

The popular methods for studying the macroscopic and microscopic appearances of the epidermic fungi have been limited to the tube and plate cultures and their modifications on various culture media, and the hanging drop of bouillon ably demonstrates the structural formation of the growth

By the plate culture Sabouraud, Colcott, Fox and others have suggested a classification of the tinea by their clinical appearances and their behavior on solid media Although they have distinguished certain of the parasitic growths, yet their differentiation from some of the common molds which form cultures not unlike the growth of the trichophyton, can only be corroborated by the microscope

Smears from cultures and cover-glass impressions only suggest stages of a growth and forms of fructification, without a complete history of vegetation

The method which I have entitled cover-glass cultures consists in culturing the parasite on a cover-glass using any nutrient media desired, placed in a moist chamber and incubated at the room temperature

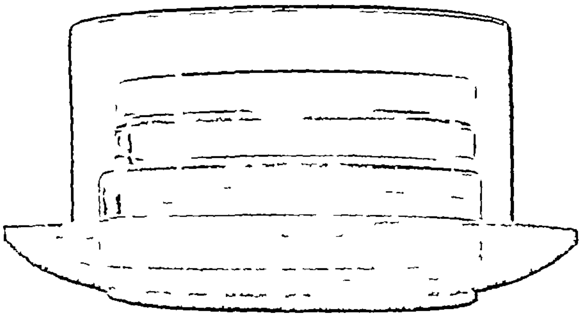

Fig 1 —Moist chamber for cover glass cultures

The advantage of this method over the hanging drop consists in the facility for observing the development long after the possibilities afforded by the latter, and by providing a method of registering various stages by staining and mounting

These specimens exhibit the beautiful arrangement of the formation of mycelia from spores, the growth of the colony above and below the media and the character of the fruit-bearing bodies or conidia, without disturbing the picture as it occurs in life

The scheme consists in placing a drop or two of culture medium on a cover glass which has been passed through a flame If solid medium is used, it must be liquefied by gently heating and then dropped on the cover glass with a platinum loop The hair or scale is then embedded while the medium is soft I generally prepare from four to eight cover glasses for each subject These are cultured in specially prepared moist chambers, which consist of a shallow glass dish furnished with a circular barrier of glass, one-half inch in height separating it into two distinct compartments and affording a shoulder over which is fitted a thin glass dish three inches in height In the inner compartment are placed Petri dishes holding the prepared cover glasses (Fig 1) Moisture is produced by keeping lime water in the bottom vessel outside the hooded barrier This excludes the air and prevents evaporation of the medium The dishes must be replenished with water frequently

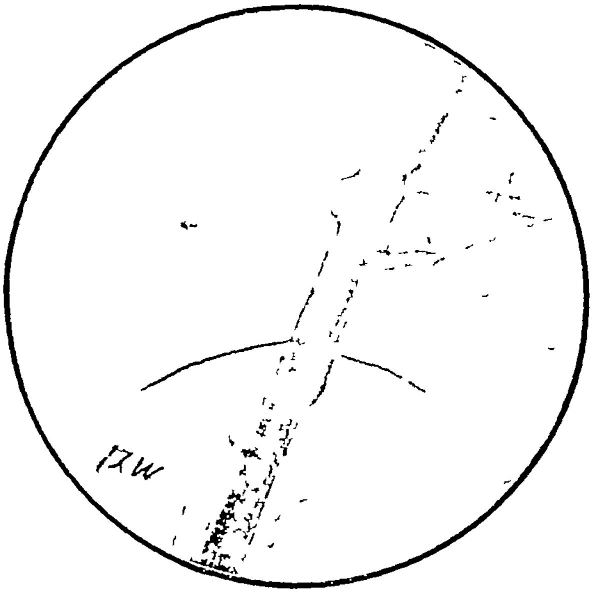

Fig 2 —Hair from small spored fungus demonstrating the process of budding

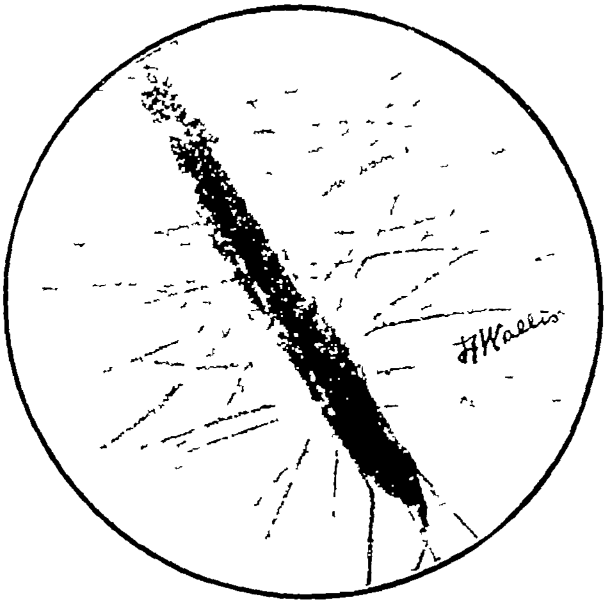
Lime water is preferred, as it precludes the possibility of contamination This is further prevented by packing a rope of cotton in the water around the cover, a precaution invaluable if the water should become vaporized This has not infrequently happened in my experience



Fi —Same hair as Fig 2 but at later stage

I have sometimes found it necessary to prevent drying of the medium by placing the cover glasses on moist circles of blotting paper in each Petri dish

Room temperature is sufficient for the growth of the epidermic fungi and less favorable for contaminations that flourish above that point The average period of

The mode of application of an ointment must vary greatly, according to the purpose for which it is used Thus, when an ointment is used for lubricating, as in ichthyosis, xeroderma, or in a slight general eczematous state, the soft ointment should be taken on the palms and the body freely anointed, with friction, morning and night, until much of the ointment has been absorbed Also in the treatment of scabies the appropriate ointment should be rubbed in, with the palms, over all the affected parts, and even for half an hour, until it has well penetrated the furrows made by the insect, and a considerable quantity should be left on, so that the underclothing becomes pretty well saturated with it

On the other hand, however, on a more or less raw, eczematous surface such a procedure would be anything but beneficial, and the ointment should be thickly spread on the woolly side of lint and firmly bound on the part with as light a gauze bandage as possible The same is true when it is applied to such a lesion as pemphigus or an ulcerating surface In this latter case, however, it is often well to spread the ointment on very thin layers of absorbent cotton, held on the hand, which may be made to fit an uneven surface, and on removal they will come off easier, without tearing the newly formed granulations This method is also peculiarly satisfactory in eczema about the anus, and in hemorrhoids, as it can be well tucked in and keeps its position

Between these two extremes there are varying degrees of active application of ointments, and patients must be instructed just how to use them or much of the benefit will be lost Thus, in parasitic diseases of the scalp, after clipping the hair very short, it is often well to apply the ointment with a stiff stencil brush, with considerable friction, working it well into the follicles, and the same mode of application is valuable in hard patches of psoriasis on all parts of the body

Again, in old patches of eczema there is often much benefit from a greater or less friction with the finger, or often with a bit of flannel with the ointment, after which the patch is covered with the same spread on the woolly side of lint and bound firmly in place In many cases of eczema or psoriasis about the hands it is almost impossible to make any progress unless the proper ointment is kept bound on the affected part all the time, night and day, for a while

In itching conditions it may be necessary to renew the applications of ointment many times daily, and in eczema of small children the direction should be to replace it as often as it is rubbed off or the dressing becomes at all deranged

In general itchy conditions as pruritus and urticaria, it may be necessary to make applications of an antipruritic ointment many times day and night

Often one sees very poor results in the using of ointments, resulting from the coverings or dressings which are placed over them It is not at all uncommon to see a diseased surface to which ointment has been applied, covered with old linen or surgical gauze, which readily absorbs the greasy portion of the ointment very shortly, and leaves the affected portion dry, perhaps coated only with the mineral or other ingredient This is not at all conducive to the healing of the part

As has been already mentioned, the best results are obtained when the proper ointment has been spread thickly on the woolly side of surgical lint, or spread on very thin layers of absorbent cotton, and bound firmly on the part

Many errors continually occur unless careful and explicit directions are given by the physician in regard to the removal of ointments and the subsequent treatment of the diseased surface It seems to be the universal idea that such should be frequently washed, and one continually finds healing prevented by the application of soap and water, daily or oftener, when with proper use of the same ointment good results followed

Rarely, is it advisable to wash surfaces which are at all raw, and all the cleansing necessary may be accomplished by the gentlest wiping with absorbent cotton Much harm is also often done by a rough removal of ointments and dressings When the latter adhere too closely it is generally because there has been too little ointment used or an improper covering made If on removal of a dressing there is much ointment on the skin which it is desirable to remove, this can often be best accomplished by means of a dull knife, if gentle wiping with absorbent cotton is not effective

INDICATIONS AND CONTRAINDICATIONS FOR THE USE OF OINTMENTS

It is not always an easy matter to know just the exact indications for the employment of this or that kind or strength of ointment, or, for any ointment, in preference to some other kind of dressing, and disappointment will occasionally follow the best directed efforts In some acute inflammatory conditions of the skin lotions and powders suit far better than ointments of any kind while in the more chronic conditions, with dry, rough skins, ointments are, of course, called for

The exact kind and strength of ointment can be determined only after a careful study of the skin, lesions present, and their acute or chronic state or condition, and also after a full appreciation of the character of the skin of the individual under treatment

In general, a thin, delicate skin, especially in one with a light complexion and hair will bear and require much milder applications than a thick, tough skin, especially in a brunette

The single or localized patch of chronic eruption will, of course, bear and require much stronger applications than an acute or generalized eruption While the sensations of the patient will commonly determine the continuance or disuse of an ointment, and great harm is not often done by too strong applications, our efforts should undoubtedly be directed to securing an application which will be effective and accomplish the end desired, if that be at all possible

Every point in a case should, therefore, be carefully weighed and the indications and contraindications looked for and appreciated, before determination is made as to the proper ointment to apply The almost universal use of zinc ointment is largely explained by its relative harmlessness, on the principle of the Irishman's holy water, who explained that, "if it does you no good it will do you no harm" This, however, is a poor principle to go on in the treatment of diseases of the skin, which often require very active measures for their removal, and, as before remarked, he is very poorly equipped for their treatment who knows only zinc ointment

In concluding these brief practical notes on the use and abuse of ointments, for the general physician I must utter the caution that we have been considering only one side of the great subject of the treatment of diseases of the skin, and one which is often the least important All local measures are constantly found to be ineffective unless proper and adequate internal and general treatment is adopted and earnestly and faithfully carried out

These results can be accomplished by combining the clinical picture and the microscopic findings with the cover-glass and plate cultures In studying the trichophytons the three classes, according to the doctrine of Sabouraud, should be observed

The microphotographs represent a few of the variations in the growth of the microsporon and the megalosporon, and the two forms of the common molds which not infrequently contaminate our cultures

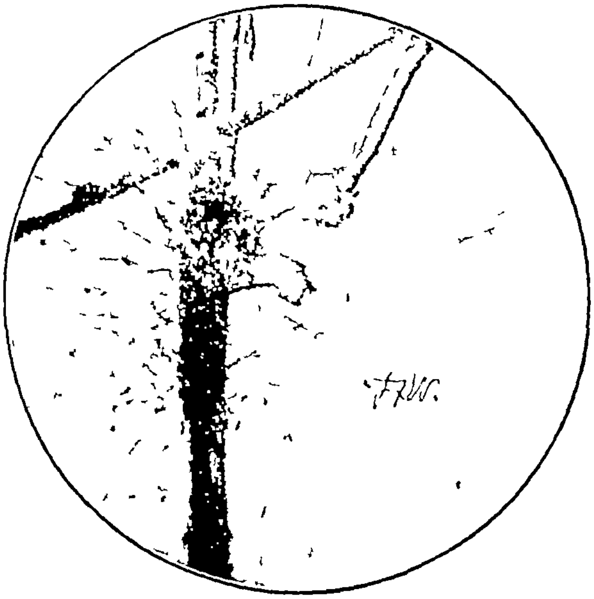

Fig 8 —Hair illustrating an unusual form of kerion

Figures 2 and 3 illustrate the development of the fungus from a hair which clinically and microscopically belonged to the first of the three classes of Sabouraud Figure 2 represents a budding occurring on the shaft and the root after the first twenty-four hours' growth Figure 3 exhibits a sprouting of the bud later, showing a number of sprouts tapering from the hair to the margin of the culture, there expanding into numerous filaments, also a dense network of straight mycelial threads are seen radiating from the hair to the margin

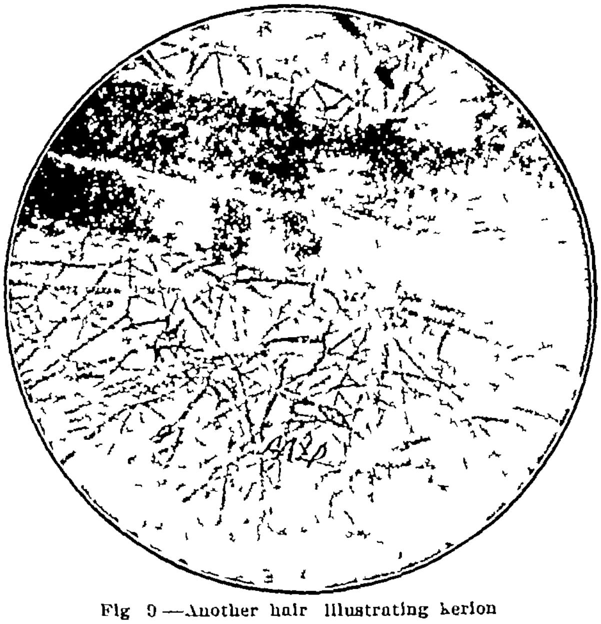

Fig 9 —Another hair illustrating kerion

Figure 4 shows a hair after five days' incubation, taken from class 1 Figure 5 represents a cultured hair, also from the small-spored variety, after forty-eight hours' growth, with straight mycelium Figure 6 shows a hair after five days' growth and corresponding to class 2

Figures 7, 8 and 9 belong to class 3, and illustrate an unusual form of kerion, the lesions consisting of numerous small abscesses invading the greater portion of the scalp In some instances they were not unlike favus, and a few were clinically diagnosed as such The patches are conspicuous by the complete loss of hair and an apparent depressed scar All cases have recovered in less than a year, with a complete restoration of the hair

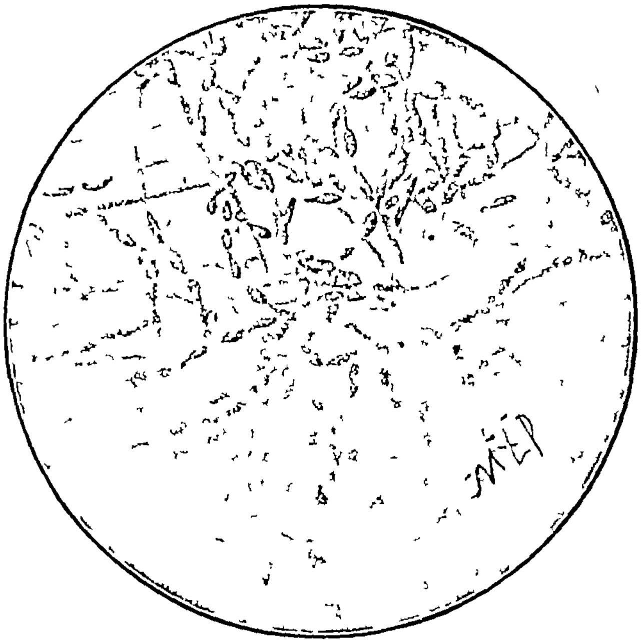

Fig 10 —Ribbons of conidia after culture

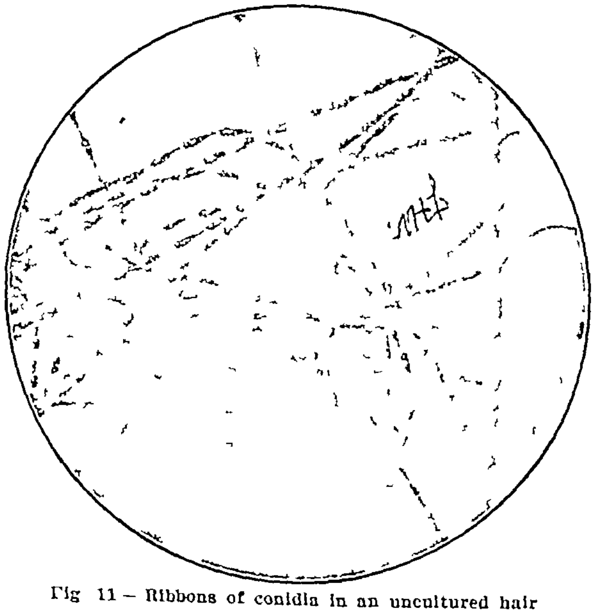

Fig 11 – Ribbons of conidia in an uncultured hair

Out of seven cases observed, five were girls, the eldest were 16 and 17 years of age The history and description of these cases will be the subject of a paper which will be published later

Figures 10 and 11 illustrate ribbons of conidia or chlamydospores frequently seen in cover-glass culture. Figure 9 is a microphotograph of a culture, and is same process found in an uncultured hair after digestion in a solution of caroid and stained

Figures 12 and 13 represent two molds Figure 11 is a living unstained culture of penicillium photographed from above, and Figure 12 a variety of aspergillus All specimens are from stained preparations, except Figure 12

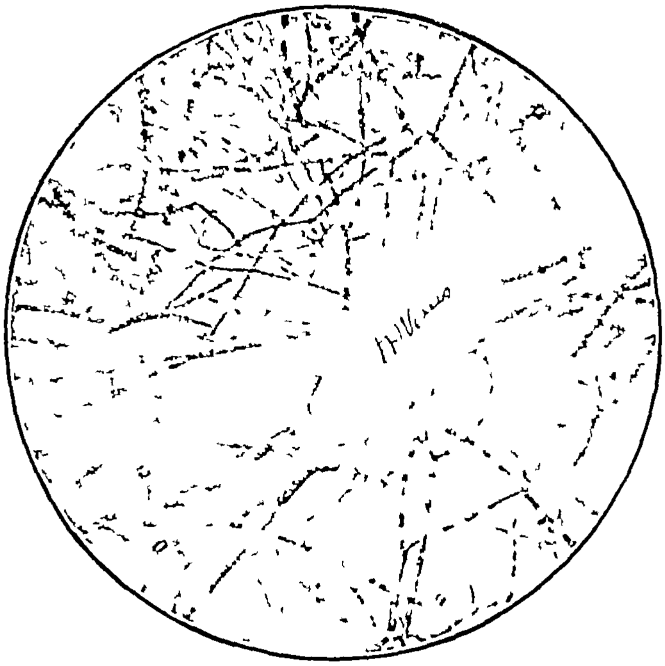

Fig 12 —Unstained cover glass culture of aspergillus

DISCUSSION

Dr Jay F Schamberg, Philadelphia—I have seen some of the cover glass preparations made by Dr Wallis in this ingenious manner, the method appears to facilitate the study of the various pathogenic fungi, particularly those that develop in hairs The photomicrographs illustrate the manner in which the mycelial threads grow out through the hair shafts into the surrounding culture medium

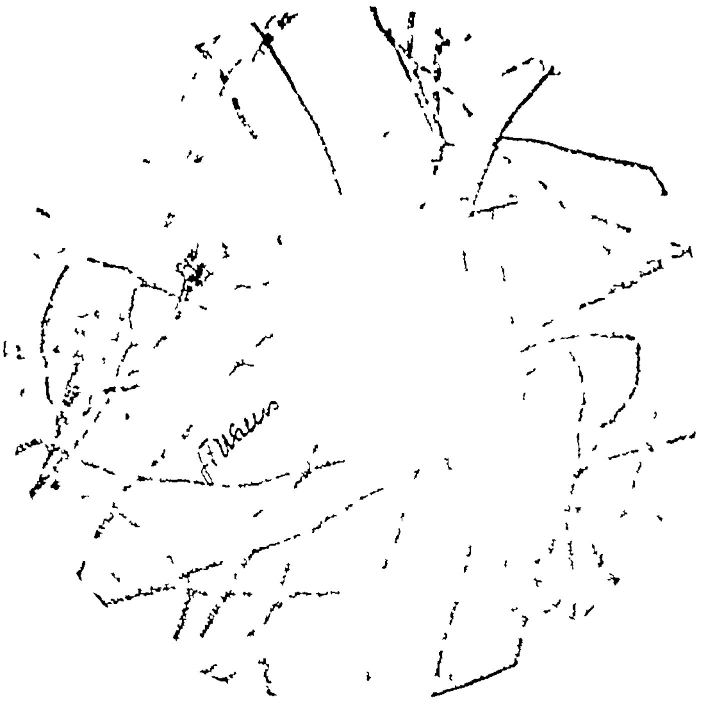

Fig 13 —Stained specimen of aspergillus

Dr. W S Gottheil, New York City—I had occasion to study contagious fungoid scalp disease when I was consultant to a large orphan asylum in New York some time ago The trouble had been prevalent for some time before my attention was called to it, and 460 cases were found among the 900 inmates Some idea of the importance of an outbreak of this usually trivial disease under these conditions is shown by the fact that it nearly led to the permanent closure of the institution, that *it took* eighteen months to eradicate, and that it cost $30,000 for the hire of and fitting up of buildings, physicians, nurses, etc We did a good deal of culture work, and finally came to the conclusion that parasites indistinguishable from the trichophyton could be obtained from the scalps of all the children, even those who were apparently unaffected Whether the fungus in these latter cases was attenuated or not I do not know, but we finally abandoned the culture test as entirely unreliable

Dr L Duncan Bulkley, New York City—It is interesting to see, after many years, the same plan gone back to which many of us used before culture methods were known Many years ago, twenty or thirty, I used the only way we knew of then, growing the culture on a plate and regulating the temperature of the room by the heater, and I have watched the growth of the parasite exactly as in the pictures presented by Dr Wallis I think this brings up a very practical matter and is a desirable statement When a man doing scientific work shows the general practitioner who is not up on bacteriology in general how he may begin in a certain way with an ordinary slide and cover glass and learn about vegetable parasites, this Section is doing what it is intended it should do, namely, helping the general practitioner to understand these things

Dr J F Wallis—I am interested in hearing that others have been before me in this work, especially Dr Bulkley I thought I was entirely original in this line of work until I read Dr Unna's paper, published in 1888, and I still believe my process differs from others, as it enables one to preserve the various stages of the growth as well as to study the living colony Dr Gottheil's experience in finding cultures from normal hairs proves that growths from other methods are not reliable It was this difficulty that suggested cover glass cultures which enables one to observe the spores within the diseased hair develop into mycelial threads and this, I think, without doubt demonstrates the cause of the disease To make the experiment more perfect I think it prudent to cleanse the diseased area of the scalp with cotton and alcohol, and this is an excellent scheme to collect the hair stubs, as they can be readily found on the cotton when they can not be seen on the scalp or epilated with forceps This I also depend on as a test, and in my experience it is diagnostic I depend on this test as a means of studying the progress of treatment

NEOPLASM (EPITHELIOMA) OF THE PULP *

V A LATHAM, MD, DDS, FRMS
ROGERS PARK, ILL

The great importance of this subject from a clinical as well as a purely pathologic point of view must be my excuse for presenting this rather incomplete study It is with diffidence that I put the case on record, for in looking through the literature at my command I have so far been unable to locate any other like condition If we exclude the hypertrophies which have been described under the heading of "Polypus of the Pulp or Tooth," then I am led to the supposition that this may be the first case recorded of an exceedingly rare condition In reviewing the literature, Ziegler[1] speaks of "tumors of dental tissue formed in later life, and described by dental pathologists as odontinoids"[2] Accordingly as they consist of enamel, dentin, cement, or a combination of these, they are classified as enameloid, enamelodentinoid, dentinoid, dentino-osteoid, or osteoid[3] They are all small, often to be recognized only by the aid of the magnifying lens They are flat, round, pear-shaped or warty in appearance The first three-named varieties grow from odontoblasts and arise from the pulp of the crown and from that of the root, generally in connection with caries, under metallic fillings, or as a result of periostitis mechanical injuries, abnormal retention of teeth or senile degeneration The osteoid form grows from the pulp and from the periosteum, and is developed from osteoblasts "Sarcoma fibroma and myxoma are in rare cases developed from the pulp as the tooth is being formed Such growths, and particularly the sarcomata and fibromata, are, however, much more commonly derived from the periosteum of the dental socket or alveolar process, from the bone marrow or from the gum itself" (Ziegler)

Boedecker[10] states that the only known tumor of the pulp is malignant myeloma, as first described by C Wedl Boedecker adds one other example, but unfortunately nothing was known concerning the history of the pulps affected

In both cases, as seen by microscopic examination they were the so-called round sarcoma, or, as Boedecker prefers to call them, lymphomyeloma The term myeloma is used synonomously with sarcoma, some authorities objecting to sarcoma on account of its derivation from the word "sarkos" (Greek, flesh), whereas myeloma means what these tumors in reality are medullary tumors When combined with epithelial as well as connective tissues, we must not forget that they are termed "medullary carcinoma," and in some cases may lead to a wrong diagnosis

Dr Juan M Alberdi,[11] Madrid, says, under affections of the dental pulp "The organic affections consist in tumors, which reside in this organ The tumors are hypertrophied productions, brought about by the simple hypergenesis of the normal elements of the tissue " The tumors are always the consequence of some lesion, especially penetrating caries, with exposure of the pulp They are smooth, of a grayish color, and sometimes of considerable size, covered by a pellicle, which is only a thickening of that which covers the normal pulp The treatment consists in removal of the pulp

11 Alberdi Dental Cosmos, p 916 1902 Third International Dental Congress

Dr A Pont[12] (de Lyon) mentions a case of tumor of the dental pulp without caries, which is not a tumor pathologically speaking, but a polypus, or primary hypertrophied pulp with secondary inflammation without power to form secondary dentin, but which has absorbed the ivory dentin, which properly belongs to the tumor division as seen so often in the osteosarcomata and might incline one to place it in this group To what it was due is not clear, as it could not have been a chronic or hypertrophic pulpitis, there being no history of pain or caries It might have been an aneurism of the pulp, but absence of hemorrhage excludes that hence we will call it a hypertrophy of pulp with total absorption of the dentin without caries

When we review the histology and gross anatomy of the pulp and note its close relation with the connective tissue origin we easily see its liability to almost every known disease Its peculiar formation enables it to supply the nutritive needs of the tooth with the vascular and nervous endowments in which it is particularly rich

The study of pulp diseases is best made by obtaining the affected teeth immediately after they are extracted Great care is necessary that an observer be not led by his preconceptions Just opinions are arrived at only after a thorough examination and by comparison with many other similar cases Diseased conditions of the pulp are to be studied in the pathologic associations of inflammation trauma and new formations

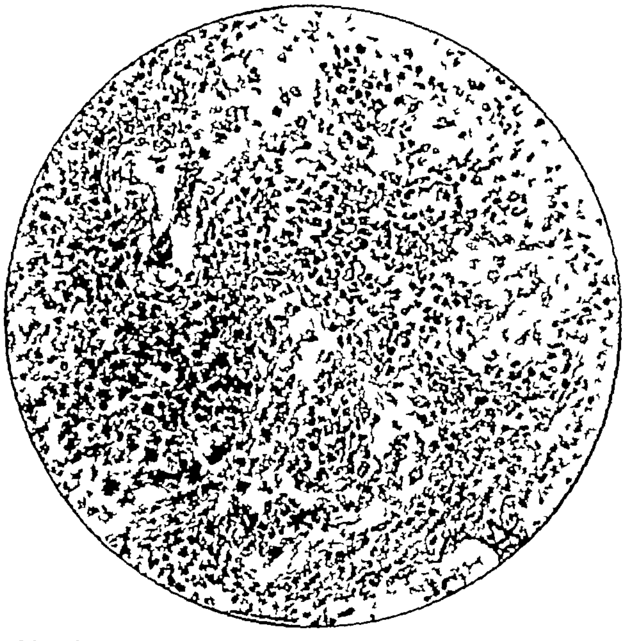

Fig 9—T S pulp nearer to the center ×2 Showing the inflammatory condition and the scattered cancer cells

Albrecht, in his monograph on "Diseases of the Pulp follows these divisions (a) disease of nerve (b) disease of blood vessels (c) disease of secretion To-day this will avail nothing as it is founded on no anatomic pathologic observation and only confuses by the intermixture of terms which is bound to exist

When we consider the position occupied by the teeth at the entrance of the alimentary tract the change of temperature varieties of food continual changes in blood pressure as a peripheral area and (in my mind one of the most important conditions to explain pathologic changes in their structure) liability to faulty development, fissures, cracks through acidity, abrasion, erosion, caries and the almost sure entrance of bacteria, as well as the relation and condition of surrounding structures as gingivitis, and the close effect of constitutional and systemic conditions of health is it any wonder we have hyperemia, which may readily be followed by more or less pulpitis, the quick follower of any irritation? Not always does it happen however, that pain does follow pulp exposure of the peripheral tubuli even when the inner aspect of the tubes is seen in a hyperemic state, the pulp is often found in a fair state of resistance The conductors of irritation, the odontoblasts, are common in their relationship to tubules and central organs, the filling up of these tubes and shrinkage of these cells break up the line of conduction, and this constitutes self-protection, then secondary deposits occur, and less pain usually follows If the condition progresses, we may have a pulp exposure, with all the signs and symptoms of pulpitis Pain is not necessarily an associate of the inflammation

When a pulpitis has been of long continuance the pain seldom is found restricted to the tooth but is apt to diffuse over all the trigeminal tract Sympathetic neuralgias are not the sequences alone of pulpitis one of the commonest causes being erosion just under the gingival margin

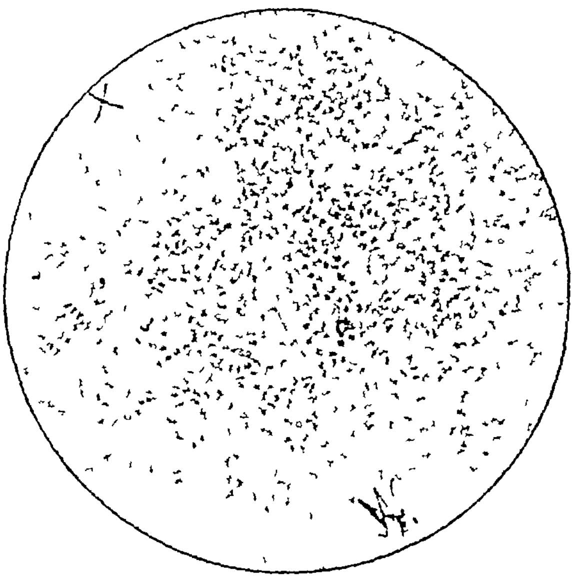

Fig 10—T S pulp following Figures 7 and 8 ×143 Showing medullary type of growth Multinucleated cells

Baume[13] considers pulpitis is rare in children, and only occurs when caries has attacked the organs before absorption begins

There are many sequelæ of inflammation which bear on the etiology of neoplasms 1 Chronic pulpitis, which may even be the primary condition 2 Suppuration 3 Hypertrophy 4 Gangrene 5 Periodontitis 6 New formations In chronic pulpitis we have little to distinguish between such as are inflamed or not death of the pulp following very rapidly in some cases There is no vital resistance but an unresisting decomposing greasy mass, which easily explains the loss of pain during death of the pulp

Suppuration—This is indicated by a sense of fullness uneasiness and weight and sometimes pulsation or boring pain which may be of slight degree in some cases, but may be accompanied by edema in and about the face in others This is one of the commonest forms of termination of chronic pulpitis Scanty watery pus, or pus of an acid nature is often met with where we have some constitutional disease, or where disease of the overlying parts has preceded or caused suppuration When pus is sealed in a cavity for any length of time, without external agencies, we find it very much thicker, pasty, and with a vile odor of putrescense, microscopically it is very rich in fat

---

[12] Pont A J Odontologie Sept 17 1902 Dental Cosmos Nov 1902 Transl Ash s Quarterly Circular Dec 1902 Second report with microscopic findings in J Odontologie May 0 1903

[13] Dr R. Baume Lehrbuch der Zahnheilkunde

Gangrene may rapidly follow suppuration, the nutritional cells becoming pus The conditions due to congestion have been followed, and gangrene succeeds the high tension point of hyperemia the breaking up of the cell walls passage and transformation of the cells the coloring the tooth and the tissues melting down surely if slowly until all are destroyed fat drops running in all directions, and even covering all the nerves and vessels and ending in a dark colored greasy putrid mass—sphacelus, or tooth discoloration Dry gangrene is meant when evaporation of the circulatory secretions of the tooth has occurred.

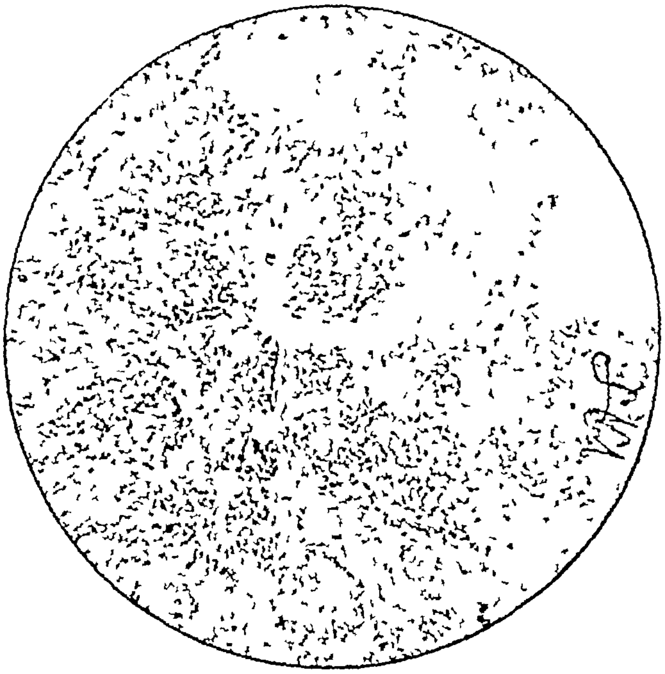

Fig 11—T S pulp continued *from Section 10* Medullary masses all through with a typical epithelial arrangement in the lower area Fragmentation ×137

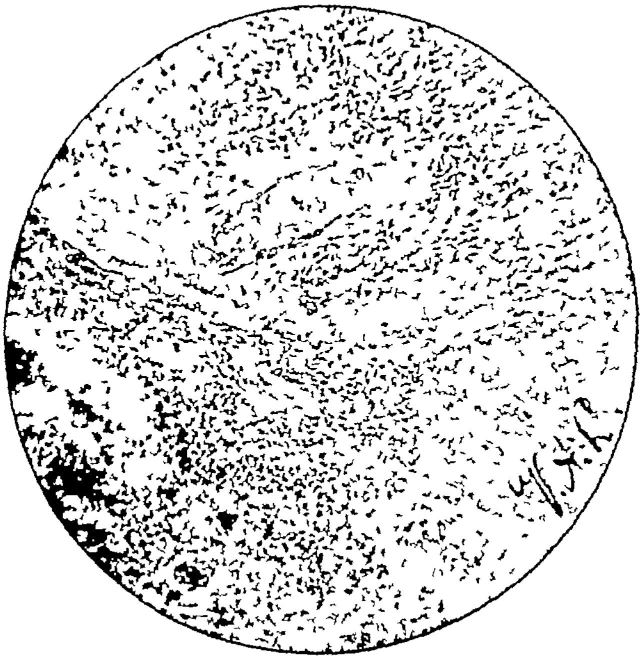

Fig 12—T S pulp ×137 Showing the change from the closely massed areas to the epitheliomatous cell nests and the pressure points surrounded by fibrous tissue—détritus

Hypertrophy—Inflammation may also cause a numerical increase in its constituents (hyperplasia), as well as hypertrophy, and form an enlarged mass so often and erroneously called a tumor True, the increase in the new growth is allied to the histologic structure in its cell elements and becomes a polypus resembling gum tissue, only projecting from the *interior* of the pulp chamber Microscopically, we see connective tissue, the vascularity being a characteristic feature The nerve element being wanting, sensibility is often lacking—*unempfindlich* Growth is rapid and often recurring readily, resembling malignant growths

Salter speaks of a "sensitive sprouting of the pulp" differing very little from the above, except that it is clearer and softer and its vitality implies a more abundant nerve supply It is often relieved only by extraction of the tooth

Romer[14] has reported an examination of thirty patients with polypus, and gives three layers of granulation tissue 1 Outer layer of pus cells 2 Wider zone of endothelial cells, and of capillaries with the appearance of gland strata 3 Strong tissue, with enlarged blood vessels and containing many round cells

When the teeth are extracted they are placed in 10 per cent formalin and decalcified in 33 1/3 per cent solution of formic acid They are cut in half with a razor and the part wanted embedded in celloidin and stained by any dye as alum-hematoxylin, and picrofuchsin (Van Gieson) or by *Weigert's method*

In the head of the polyp no nerve fibers were seen, but in pulp chambers and root canals were nerve bundles, *varying according* to the degeneration found, which consisted usually of fibroid elements seen best in teeth whose pulps have been exposed by fracturing the tooth *in faulty extraction* In the case under consideration there was little to note as being unusual

The patient, an elderly woman, aged 56, stout build, neurotic type, with signs of bronchial irritation and asthma (two sisters having died of cancer) called to see me regarding a partial plate After examination I advised that the few remaining teeth be extracted, as she gave a history of continued neuralgia around the face and head The teeth were scattered in the mouth, and only the right upper first premolar and cuspid seemed peculiar, the former having a queer reddish color, no carious spots or other evidences of decay The mouth was very cleanly kept, slight irritation of the gingivæ around the teeth and a feeling of uneasiness about the premolar On percussing, I found that the nerve was not dead, but evidently congested On extraction, hemorrhage was free and the tooth seemed to give way reluctantly, with a feeling of pulling from the apical attachment (hyperplasia cementum) I dropped it at once in warm saline solution, and then extracted the cuspid, which was an oddly shaped tooth, of a queer greenish white tinge, so noticeable that the patient many times said people asked what was the matter with it The cuspid was exceedingly difficult to remove, and on its coming out a dram of yellowish clear fluid oozed from the alveolus The apex of the root was covered with a thickened layer of peridental tissue, and I wondered if it was an abscess sac that had ruptured, the foramen showed a whitish thread hanging as the pulp, and I saw no evidences of suppuration, but some hypercementosis So I preserved it in salt solution The socket I carefully cleansed with peroxid of hydrogen, there was no effervescence to speak of, except when bleeding Then I probed the cavity and finally curetted it as thoroughly as I could, applied tincture iodin, and then 95 per cent carbolic acid, and plugged with gauze and wool This I did for nearly a week, and then allowed the cavity to close It healed steadily on the slow and gradual withdrawal day by day of the gauze tampon The patient so far (after three years) has had no recurrence nor trouble, and seems much more comfortable using no upper plate yet, as she prefers to wait

---

[14] Römer Ueber Pulpa Polypen der Zahne Corresp Blatt f Zahnarzte C Ash Berlin Jan 1892

The teeth were removed from the saline solution and carefully opened one longitudinally, and the cuspid transversely about half way, and the root longitudinally under normal fluid till appearances were noted, and then it was changed to Zenker's solution The cuspid had a fairly solid pulp, whitish green It looked like a fibroid, and was springy to the touch like a myxoma I made microsections and reproduce some photomicrographs from them Taking the pulp at different levels, we find it complex and offering an unusual appearance

Several points are worthy of note (Figs 1-2) 1 Evidence of granulation tissue and pulpitis 2 Slight sclerosis or fibrosis 3 Slight hyaline degeneration in this area 4 Small vessels surrounded by fibrous thickening 5 Many polymorphon leucocytes were scattered through-

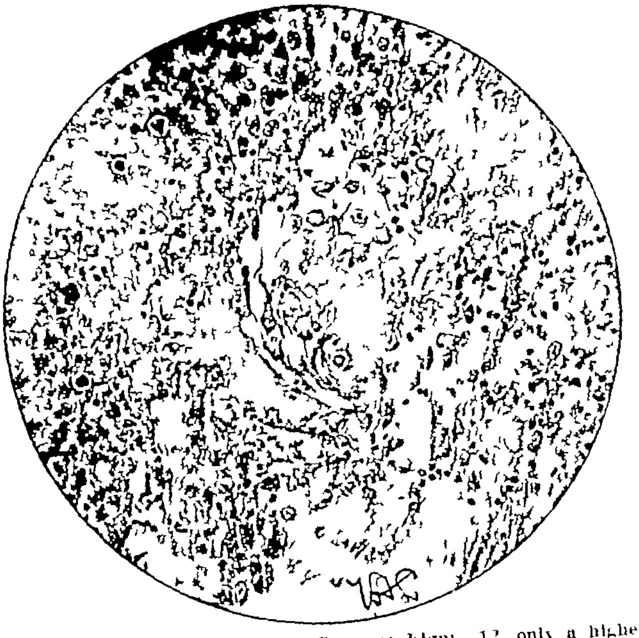

Fig 13—T S pulp ×225 Same as Figure 12 only a higher magnification to show the epithelioma with layers of cells Nucleated characters plainly seen Yeast infection

out, in some places massing together like a round-celled infiltration and mixed in with bands of fibrous trabeculae (Figs 2, 3 and 4) 6 Near the outer edge were more deeply stained cells and better formed fibrous tissue, which gave a more homogeneous appearance to the cells, and at one side was a dark bluish irregular body a calcospherite or pulp stone longer than it was wide and with a poorly stained area around it (Fig 1) At one edge of the specimen was an almost glistening hyaline mass of cells, inflammatory, and with some cells much larger than others and multinucleated lining the fibrous stroma spaces, almost like scirrhus cancer (Figs 5 and 6) Some of these cells were massed in cluster-nests showing signs of considerable pressure some cells staining a pale hyaline pinkish color, with the nuclei taking a darker stain like cartilaginous cells others appearing horny and taking no stain A number of dyes were used prominently hematoxylin and eosin Van Giessen and Ranvier's picrocarmine and logwood picrofuchsin and nigrosin safranin Unna's polychrome-methyl blue

A method that will be found very useful for gum tissue, polypi and epithelial structures is one modified and suggested by W R Smith, M B Stain the section on the slide with hematoxylin and alum carmine, wash with water and put on the slide, dehydrate with absolute alcohol, stain a few seconds with a saturated solution of saffranin in anilin oil water, of which most is removed with blotting paper, run over the section absolute alcohol for a few seconds and immediately drop on clove oil, mount in Canada balsam in xylol or chloroform Great care is required in the washing out, it must only be partial Too little alcohol in the washing leaves the stain in the normal tissues, and does not differentiate the cell nests from these or from other epithelial structures Too much alcohol removes the whole of the stain from all pathologic and normal tissues If sections are cut fresh, it is much harder to stain with hematoxylin and to dehydrate For fresh sections, soak a few minutes in 4 per cent formalin or methyl alcohol and then use alum carmin and wash thoroughly in water, and dehydrate The carmine stains faster if gently warmed In studying these specimens we must clearly note

1 Whether normal non-pathologic growths of epithelium in the form of processes are growing inward from an epithelial surface, e g gum, epidermis, mucous membrane, pulp or glandular organ which can resemble an epithelial pearl when cut in some ways

2 Pathologic processes, papillary prominences, epithelial columns of homogeneous masses of epithelial cells with ovoid nuclei (papillary prominences of Lebert), which may be found in the surrounding tissue, and simulate cell nests Neither of these correspond with Billroth's classical description of cell nests What distinguishes these masses in their earliest known form? (Figs 7 and 8)

They appear at first sight like spherical or oval cysts from 1/100 to 1/500 of an inch in diameter walled in by irregular fibrous tissue, and containing granular matter, nuclei or cells within them They may be in cluster or cylindrical, their nuclei are shriveled or not visible, contents often granular

The termination in horny material is an extreme form of specialization, and such is not the destiny of all cell nests Indeed, the study of these extreme forms is much desired, for observers have thus been misled as to the true nature of the structure and mode of growth of cell nests in general[15] (Fig 13) In all probability epithelial cell nests start from one cell, by division and subdivision, except in such a disease with large pearls, as seen by Hamilton[16]

In Figures 7 and 8 we find a single cell with two nuclei standing out, around it various sized cells are massed, forming an early cluster and surrounded by one outer layer of cells, in places, only a single cell and small cohorts of a few cells each In some places we find here and there a thickened capillary or arteriole, showing well-marked cells lining the endothelium (Fig 7) here and there a large cell and nucleus or an alveolus filled with a cluster of cells almost forming an island (Fig 10)

We find masses like those just described mixed in with the small-celled infiltration of Virchow indicating active proliferation and irritation with the intermediate areas breaking down or staining only poorly but with here and there well-marked nucleated cells Lying near these masses we see some typical cell nests with granular détritus among them, singly and in groups. How these cell nests grow is yet to be understood. Paget[17] is in favor of the theory of the growth being from one central cell, and Snow,[18] who, with others, gives us a theory of surrounding pressure, says "a small area of cells always appears as the original point of the globe, never a single cell." (Figs. 9, 10, 12.)

---

[15] Woodhead's Pathology second edition 1885 p 481 third edition 1892 p 174

[16] Text book of Pathology 1889 part 1 p 406

That this specimen is a carcinoma epithelioma, is very evident. It certainly can not be classed, like Wedl's and Boedecker's cases, as a lympho-myeloma or round-celled sarcoma, for it certainly possesses epithelial nests, fibrous trabeculæ, and stroma, lined with large cells, granulation cells of the polynuclear type, degeneration and a reaction to dyes that marks the carcinoma group. (Figs. 6, 7, 11, 12, 13.)

"In polypus of the pulp the parenchymatous connective tissue is the seat of the proliferation described as sarcoma of the pulp, in which the parenchyma is gradually destroyed, and indicated by the absence of nerves and the altered character of the blood vessels. As the sarcoma is located on the outside of the remains of the pulp it serves in a measure to protect the latter."[7]

The study of the odontoblasts is a very vexatious one, as on account of their close relation to the dentin it is difficult to procure good sections without decalcifying the hard tissues, or preparing a tooth by the Koch-Weil process, which loses much valuable material, and the disarrangement of the pulp, unless this is done, renders it valueless.

In removing the pulp from its chamber the layer of odontoblasts clings tenaciously to the dentinal walls either partly or as a whole, and hence we can easily understand how little progress has been made in this study. Black[9] states that this layer of cells seems to remain unchanged in acute inflammation until combined with suppuration. This seems, judging from my own work, to be hardly the case, for the cells are seen in every state of disease, and many times are not present, showing plainly the odontoblast cells act very similarly to the ciliated cells in bronchitis, and the falling off before the pulp is very much affected shows how easily any irritant affects the deep pulpal ends of the cells, and so causes atrophy and degeneration. (Figs. 4 and 5.) Hopewell Smith also shows illustrations which correspond to my own slides of inflamed odontoblasts, showing in some a numerical hyperplasia. It would be an interesting study to make careful sections of pulps *in situ* and extracted from teeth excised in cases of neoplasms of the jaw, as myeloid sarcoma, epithelial growths, fibroma, epulis, etc., and so note if the pulp shows any metastatic deposits or any other pathologic conditions. I have a few specimens so made which exhibit many problems for elucidation, and especially as regards their origin.

In the specimen here presented it may be asked how and from what did this growth originate. The teeth were to all appearance, sound; even with an aplanatic lens nothing could be seen but the change in color, which gave me the idea of a dead tooth, and the percussion note was negative. The sensitiveness and neuralgic pain pointed out pulp and peridental irritation. Stanley Colyer[20] shows a "burrowing epithelioma from the periodontal membrane" which illustrates my section of neoplasm of the pulp very well, but he found the pulp dead and suppurating. His theory as to origin would certainly be questioned by many of the workers in carcinoma to-day. (Figs. 11 and 13.)

If we accept the theory that "like cells produce like," then how did odontoblasts produce epithelial cells, if the former originate from the stomodeal mesoblast, i. e., from the periphery of the dentinal or pulp organ? If odontoblasts could be proved as arising from the epiblast or hypoblast, many difficulties would be removed. Their nerve endings and their close relationship to the cells at the terminations of the optic and auditory or sensory nerves, not only as regards the physiology, but the morphology and pathology, their functions being allied somewhat to the glandular organs as in the stomach and intestine, namely, secretion, excretion and manufacture of chemical problems for metabolism and the situation and better development of odontoblasts at the coronal cervical part show that we have here a close relationship of epiblast and hypoblast structures. This points to the nerve impressions passing through the tubules, and shows a closer relationship to the nervous system than is usually given.

In looking over the question of treatment we must note the use of the cautery, escharotics and iodin. In this instance, the best and only treatment was extraction, and if it had not been for the usual plan of study by breaking open the teeth and making sections, the great danger the patient ran would never have been recognized, and the chance of continual watching afterward, as well as the curetting which was done, would have been lost. It is well known that arsenic has been accredited with causing epithelioma, and J. Hutchinson[21] considers that many of the cases of multiple cutaneous sarcomata may be fairly attributed to the use of iodin and its salts. When we note the frequency with which iodin is used in dentistry, externally and internally, that many patent medicines contain it and consider its use in the arts, photography especially and in the preparation of the antiseptic gauzes, we can find another point for study. The frequent stimulation used by dentists for pericemental and periodontal irritation should cause an increase in hypertrophy, gingivitis and the papilloma and epulis forms of growth to say nothing of the epitheliomata, but I think it can be shown we have less neoplasms in the oral cavity now than formerly, due, possibly, to better hygiene and methods of operating.

CONCLUSIONS

The points of interest are:

1. The freedom from urgent symptoms beyond neuralgia.
2. The great rarity of neoplasms of the pulp.
3. Lack of literature and careful pathologic and histologic study.
4. The want of further and more complete examination of the tooth structures in relation to the pathology of neoplasms of the jaw.
5. The question of metastases in the pulp from periodontal tumors.
6. The value of microscopic study should be urged in dental schools, as an aid to differential diagnosis and treatment.
7. The changes which may attend the killing of pulps by irritants and care to thoroughly cleanse the pulp canals.
8. To emphasize the better treatment and value of closing up fistulous openings in the gingivæ for fear of

ming up of Dr. Andrews' paper is the desirability of retaining the pulp in a tooth for other than formative purposes. Dr. Andrews' position on the retention of the vitality of the pulp when not diseased is probably correct. When a pulp becomes exposed there are certain changes that take place within a certain period which render that pulp as a normal organ valueless, and it might just as well be destroyed. Referring to the paper of Dr. Latham, I think perhaps the extraction of that tooth was correct, but I challenge the statement that there is no method of knowing whether the pulp has died because we have ample means at present, although somewhat imperfect, of determining whether the pulp is alive.

Dr. V. A. Latham.—I said that our means of diagnosing dead teeth was not as yet very perfect or absolute.

Dr. A. W. Harlan.—So far as determining the vitality or non-vitality of the pulp is concerned, I should contend that with heat, cold or electricity we can determine that absolutely. I was interested in Dr. Talbot's statement that abnormalities of the teeth occur from non-use. In the publication of Oakley Coles more than 50 years ago, there are shown a number of abnormalities of the pulp. It is absolutely certain that when a tooth is not in use it deteriorates either by elongation or by the growths on the external surface of the root, or that it gets out of position and the tissues around the root become so inflamed and irritated that it becomes a useless member. It is further absolutely determined that in the rapid eruption of the teeth certain changes of the pulp take place. The chewing of tobacco and the holding of pipes in place also cause changes in the pulp. When the pulp is diseased we have a formation which may be in the shape of a cyst, and within that cyst we may have a deposit of calcareous matter which is a pseudo form of tartar. There are growths around the ends of the teeth after the pulps die that may cause serious disturbance of the general system so great as to result fatally. I would therefore, conclude that when the pulp becomes exposed it should be destroyed, no matter whether it is surgically removed or poisoned; destroy it so that you will get every vestige of it out. The root of the tooth should be filled and there should be a sufficient amount of contact with the opposing jaw to keep the tooth in use.

Dr. J. L. Williams, *Boston*.—Pulps that are nearly exposed and not diseased I have proved in years of practice can be saved and means taken to protect them, but, after a pulp has become inflamed I have learned not to expect its total recovery. It may be kept comfortable, but I suppose its nutritive quality is lost, and I often question whether it is worth while to tamper with it. Some years ago I saw a case in which the pulp was exposed but not wounded. I tried a process of treatment, which I was the first to introduce and systematize. I made the softest possible antiseptic covering for it, I looked at it at the end of a month and again treated it. At the end of about a year I opened it. It looked perfectly clean, and in passing my instrument over the transparent secondary dentin there was *no sensation*. It was then filled. In two years the tooth decayed on the other side. There was some sensation on excavating the new cavity, showing that we should discriminate between an exposed pulp and a diseased pulp. I do not believe that when a pulp has its growth it does not contribute to the continued welfare of the tooth. When it can be made healthy it should be saved for the benefit of the tooth.

Dr. E. C. Briggs.—We should bring out clearly that the idea brought forward is not that one is to go around slaughtering pulps of teeth, but that, if things are in any way wrong concerning the teeth, the chances are that there is more menace from the presence of the pulp than without it. In answer to Dr. Bogue, I do not like to have the principle destroyed by his questioning one's ability to remove the pulp. I do not pretend that I can do these things, but I think the chances are that I or some other one will find a perfect way of doing this work. We are doing now a great many things that could not be done ten years ago. The underlying principle is not affected.

Dr. E. A. Bogue.—Dr. Dawbarn, in a paper on malignant growths, speaks of an operation of his own devising, viz., excision of a portion of both external carotids, after ligation and *in speaking of* that he has two or three times wondered why we as dentists did not more often observe the *incipient beginnings* of cancer. He says that sarcoma and carcinoma are acted on quite differently by his operation. In sarcoma he has had no instance up to the present in which he has felt that his operation has been a failure. In carcinoma he regards the operation as helpful only *for a short time*. That brought to mind Dr. Latham's case, which would show that it was through the circulation that carcinoma took its way, while sarcoma may more particularly be called a local condition. I hope we may have a further report concerning Dr. Latham's case.

Dr. Talbot.—There has been for several years a symposium on the dental pulp and the results have been more than satisfactory. Dr. Andrews' paper is far reaching and I fear the importance of the paper is not understood. It has *been* discussed from the degeneration standpoint, but the fact has been lost sight of that the pulp at any period of life has its influence on tooth structure. The paper is most valuable, because it leads to the point of the necessity of the vitality of the tooth. If it be *necessary*, as Dr. Andrews shows, it *must* follow that diseases of the human body have a great influence on tooth structure. It must be admitted that there is a difference between supposition that certain conditions of the pulp exist or that they have been found and actually demonstrated. Supposing a *condition* exists in the human body, to state it is one thing, to demonstrate it another. I wish all these papers on the pulp could be published in book form. It would be a most remarkable collection of papers.

Dr. Latham.—I came before this Section asking for a diagnosis, for advice and also for bibliography. My main object was to bring my contribution before the Section for discussion as to the origin of the growth. I have held this case in hand for some three years and only recently thought of publishing it. I have had experts in Germany and in England looking up bibliography for me with no success. The papers are not published in a way easy to be found, especially since the *Dental Cosmos* stopped its bibliography, and I would suggest greater care in choosing titles. I ask from what tissue did this epithelioma arise if the pulp is a mesoblastic structure?

ASCARIS TEXANA

A NOTE ON A HITHERTO UNDESCRIBED ASCARIS PARASITIC IN THE HUMAN INTESTINE.*

ALLEN J. SMITH, M.D.
PHILADELPHIA
AND
RICHARD A. GOETH
SAN ANTONIO, TEXAS

The following note is based on two female specimens of an ascaris submitted to Dr. Smith by Dr. Goeth, who had obtained them from Dr. Ferdinand Herff of San Antonio, Texas. Together with a number of other examples supposed to be of the same kind they were passed in the intestinal discharge from an adult white man in care of the latter physician, the patient stating that for several years he had passed similar parasites from his bowel (some of which were slightly larger than the two samples given his physician, but apparently of the same type) and complaining of his inability to rid himself of the pests, which however, gave him no particular physical inconvenience. Efforts to obtain other specimens since last year when these were passed have thus far been without success, and the absence of a male example renders the establishment of the full specific description impossible for the present. Moreover, the two specimens when sent by Dr Goeth had been mounted unstained in balsam on glass slides, and, from the influence of the reagents used in the balsam-mounting medium as well as from compression and division of each specimen into three lengths for convenience of mounting were not in favorable state for detection and clear recognition of many of the finer details needed in the study Sufficient data may however be determined from the material in hand to surely differentiate the worm from the known ascarides of the human intestine and to make the idea of its identification with other known members of the genus improbable Attempts to stain one of the samples for better definition of the minute structure have not been attended with any success

---

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Pathology and Physiology, and approved for publication by the Executive Committee: Drs. V. C. Vaughan, Frank B. Wynn and Joseph McFarland.

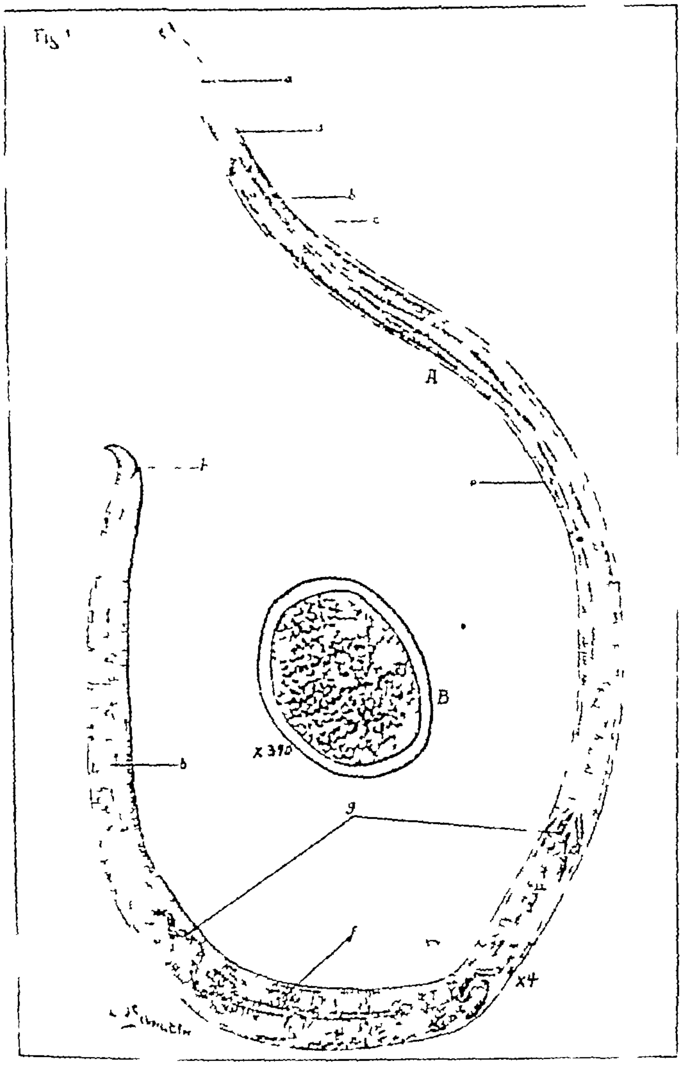

Fig 1 —A Low amplification of female *Ascaris texana* a esophagus b intestine c longitudinal cuticular band d poison glands e vulvar orifice f uterus containing ova g ovary h anus B Ovum

We hesitate to insist on the absolute correctness of the view of the novelty of the species until the description following may be verified by study of fresh material and male specimens but we feel that from the data in hand the specimens presented may at least be tentatively accepted as constituting a new species, and would suggest that it be known as *Ascaris texana*

The two specimens closely agree grossly and minutely They measure respectively 58 and 60 mm in length and at the thickest part 1 and 1 5 mm in thickness (taking no account of modification from shrinkage from the preserving and mounting reagents employed and the widening consequent on compression of the specimens) One should recall in this connection the patient's statement that other samples discharged ranged slightly larger than the ones described

The specimens when fresh were practically colorless or slightly yellowish cylindrical or subcylindrical, tapering through a long anterior half to the head, rapidly tapering from close to the anus to a slightly dorsally curved and mucronate tail the thickest part of the worm being in the region of its posterior third The cuticle is finely striated transversely, and in the compressed specimens one lateral longitudinal band may be clearly made out No alæ as in *Ascaris mystax* are recognized anteriorly or posteriorly The three lips of the genus *Ascaris* are well developed broadly conical interlabia being present reaching close to the level of the oral membrane between the lips The lips are of a rudely hexagonal shape the base forming the sixth side and the lateral and basal angles being rounded The anterior border is slightly concave and the anterolateral more distinctly so, the posterolateral convex, the anterior and posterior the smallest On the internal margin of the anterior border of the lips are a number of small tooth-like papillæ, the remainder of the free borders being entire and smooth The superior lip is slightly larger than the inferior ones, although the difference is apparently but little The pulp of this lip rises from the esophageal musculature, passing forward close to the anterior border of the lip where it is subdivided by a depression, the "saddle," into two paired lobes each of which bears four or five lobules of papillary appearance which extend anteriorly or anterolaterally An unpaired lobe projects on the inner surface of the lip in somewhat of a keel shape toward the base of the lip giving the usual triangular shape of a transverse section of the lip at this level Each of the inferior lips is provided with a pulpa symmetrical with its fellow the pulpa of the superior lip being bisymmetrical i e its lobes are symmetrical or paired with

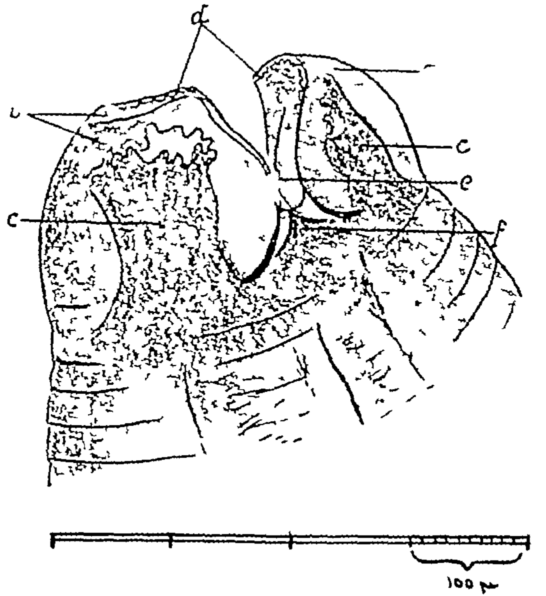

Fig 2

Fig 2 —Lips of *Ascaris texana* (camera lucida drawing from compressed specimen) a superior lip b inferior lips the left overlying the right c pulpa d denticulate anterior margin of superior and right inferior lips e keel of superior lip on inner surface f interlabium

each other The oral cavity opens directly into the muscular esophagus of long, slender flask shape, terminating 31 mm back of the base of the lips, this opens apparently by a valve arrangement into an intestine, which runs a nearly straight, slightly sinuous course to the posterior end of the worm, terminating at the anus, close to the tail on the ventral side Along the esophagus and anterior end of the intestine for a distance of 12 mm from the base of the lips apparently in two masses, may be traced a finely granular material which probably represents the so-called "poison glands" of the ascarides, and for some distance along the intestine a fine granular exterior probably represents the remnants of digestive cells The anal opening is a transverse slit 1 150 mm from the tip of the tail The number and arrangement of pre-anal and post-anal papillæ are doubtful from the specimens in hand, two well-marked post-anal ones are clear, 0 5 mm back of the anal orifice

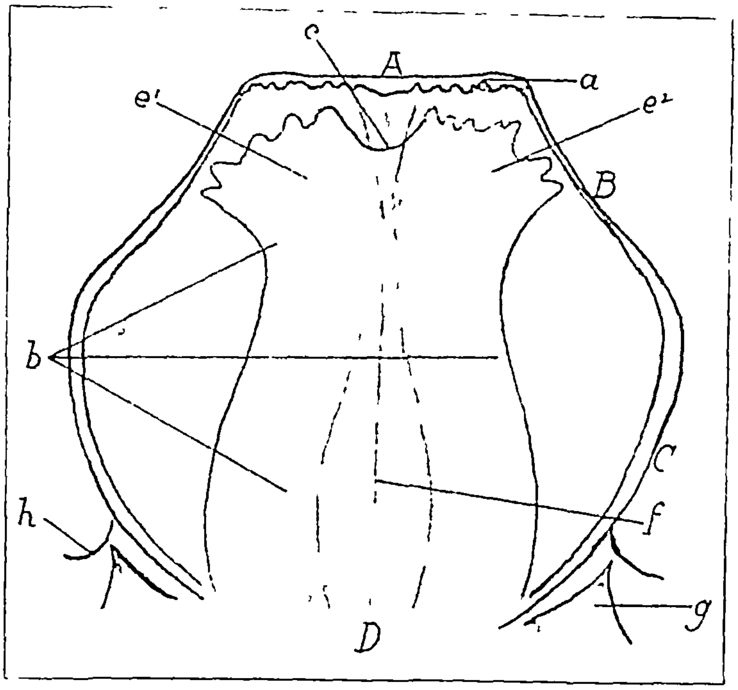

Fig 3 —Inner aspect of superior lip (constructed) A B C D anterior anterolateral posterolateral and posterior sides of same a denticulate anterior internal border b pulpa c saddle e¹ and e², paired lobes with lobules f unpaired lobe forming keel of lip g interlabium h border of interlabial oral membrane

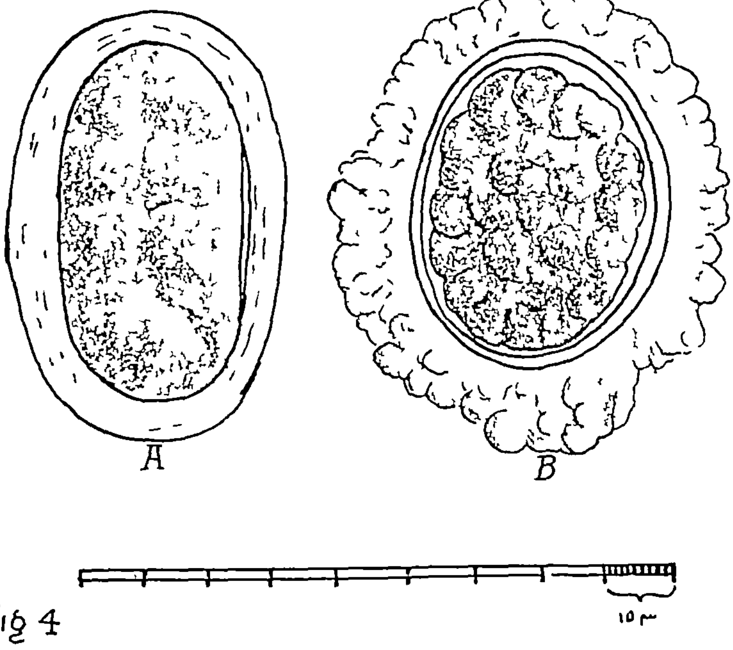

Fig 4

Fig 4 —A Ovum of *Ascaris texana* drawn from specimen in uterus B Ovum of *Ascaris lumbricoides* drawn for comparison from examples taken from uterus of formaldehyd specimen

The sexual orifice is not certainly determined because of the condition of the material, but what is regarded as such, because of the prominence of the lips and the appearance of sphincter-like folds in the cuticle about it is situated 2 cm back of the base of the lips, just anterior to the level of the uterine canal In neither of the specimens studied could the vaginal tube be traced There are two ovaries, anterior and posterior, plicated along the intestine and uterine canal Within the latter in both specimens are large numbers of ripe and often well-segmented ova, colorless, provided with a thick wall, without visible external marking or envelope as are met in the eggs of certain of the ascarides They measure 60×40 microns, with variations of 4 to 5 microns in different ova measured The interior is granular no nuclei being appreciable in the specimens at hand

Whatever other features may later from fresh material be learned of this worm, it may be without doubt placed in the series of ascarides, with toothed anterior labial border and with interlabia, a feature which, aside from other gross and minute features, excludes all ascarides at present known to be parasitic in the human intestine (which with others of the genus are unprovided with either), and which, likewise, separates it from a considerable group which with auricles and interlabia in the labial structure, fails to present such denticulate margins From other examples of ascarides which like it, present six-sided lips with denticulated free borders and interlabia, it is distinguished by the fact that it has the denticulation present only on the anterior concave border by the shape of the lip and the arrangement of the pulpa of the superior lip From its general appearance it is most closely allied to ascarides known to be parasitic in certain birds and reptiles

THE UNITED STATES PUBLIC HEALTH AND MARINE-HOSPITAL SERVICE

PART I A HISTORICAL SKETCH

(Continued from Page 462)

(D) DR WYMAN'S ADMINISTRATION (1891 TO THE PRESENT)

Surgeon-General Walter Wyman had done much for the sailor and for the service before he became surgeon general He had frequently called attention to the physical conditions affecting seamen of the merchant marine, and after he became surgeon general was instrumental in having laws passed for their benefit, notably one for the relief of the deckhands on western river boats, who, by reason of inadequate quarters were unprotected from the inclemencies of the weather When in command of the Marine Hospital at Baltimore, he exposed the cruelties to which crews of oyster boats in Chesapeake Bay were subjected and succeeded in causing amelioration of their condition As surgeon in command of the Marine Hospital at New York, he recommended and established, with the consent of Surgeon-General Hamilton, a laboratory for the study of bacteriology and pathology, which was later moved to Washington and which, under his fostering care as sur-

---

EDITOR'S NOTE.—This article began July 30 The Army Medical Department was discussed May 7 14 21 28 and June 4 geon general, developed into the splendid institution now known as the Hygienic Laboratory of the Public Health and Marine-Hospital Service

As surgeon general his intense interest in the physical welfare of the sailor in no wise lessened, and he originated and carried to consummation the idea of a sanatorium for consumptive sailors at Fort Stanton New Mexico

Owing to the lack of a strong federal quarantine law the United States in 1892-3 faced one of the most dramatic crises in its history The dreaded specter of Asiatic cholera emerged from the filth of its oriental home, and appeared in the seaports of western Europe The history of past appearances of cholera in Europe in seaports showed that an epidemic in America invariably followed, and the prophecy was made everywhere that history would repeat itself The outbreak of an epidemic of cholera in our seaports at this time would have resulted in the utter failure of the great Chicago Exposition of 1893 and the failure of this exposition would have carried financial ruin to thousands, and caused commercial paralysis throughout the entire country To meet this emergency the quarantine law of 1878 was lamentably weak The chief danger existed in immigration and the weak spot in our quarantine law was the lack of federal authority to enforce uniform requirements in regard to inspection and disinfection of ships and baggage

The power of the National Government, as expressed in that law, was restricted to aiding state and municipal quarantine authorities in the exercise of their functions The power to frame regulations under this act of 1878, it is true, rested in the Secretary of the Treasury but such regulations must neither conflict with nor override any state law or regulation existing or which might be enacted The proper uniform disinfection of immigrants' baggage being impracticable, it became evident that the only other effective safeguard would be to temporarily suspend immigration In this crisis Surgeon-General Wyman searched the quarantine laws of the various states for some uniform requirement which would accomplish the desired result He found that in every seaboard state a law existed providing for the detention of suspected vessels for periods of twenty or more days Therefore a government circular demanding the detention of immigrant vessels from cholera-infected seaports for a period of twenty days would not be inconsistent with state laws, but, on the contrary, would be aiding state quarantine laws already in force Accordingly, the surgeon general prepared a circular providing for detention of immigrant ships from infected ports for a period of twenty days This circular was promulgated by President Harrison, and while it seemed like a reversion to the obsolete practice of Venetian quarantine, it was in reality expected to temporarily suspend immigration It was rightly surmised that the immense expense attendant on twenty days' detention of immigrant vessels would so minimize the steamship companies' profits that they would be compelled to suspend the traffic for the present The effect was pronounced and startling Immigration was practically suspended, and the menace of a great cholera epidemic was removed

The absolute stoppage of immigration from any country, even temporarily, was then, as now, deemed inadvisable for obvious reasons, yet this circular effected the same result without giving ground for valid international complaint To supplement the system of detention or virtually exclusion of immigrants at our seaports resulting from the circular and prevent evasion of the law, it was necessary to establish a quarantine inspection service along the Canadian border By the courtesy of the Canadian government, officers of the Marine-Hospital Service at Quebec examined immigrants destined for the United States, and supervised the disinfection of their suspicious effects The inspection on the Canadian border extended from Maine to Dakota at all points of railroad crossing This rather drastic remedy was only intended to protect the country until Congress should meet and have an opportunity to devise an adequate system of protection under federal authority involving less restriction on commerce

Congress recognized, when that body reassembled in December, 1902, the grave national danger from cholera which had been temporarily averted by the President's circular and as a consequence passed a law, approved Feb 15, 1903, entitled An act granting additional quarantine powers and imposing additional duties on the Marine-Hospital Service"

This act of Feb 15, 1893, placed all matters pertaining to national quarantine in the hands of the service and provided for the formulation of uniform regulations to be observed by all state and local quarantine authorities in preventing the introduction of epidemic diseases from foreign countries, and the spread of such diseases from one state or territory to another

The regulations were promulgated by the Secretary of the Treasury, and the Surgeon-General of the Marine-Hospital Service was charged, under the direction of the secretary, with the performance of all the duties in respect to quarantine and quarantine regulations, which were provided for by the act The law further provides that if the states or municipalities should fail or refuse to execute the quarantine regulations, the President should appoint a proper person to execute them

Under the provisions of Sections 2, 3 and 4 of this act medical officers of the Marine-Hospital Service have been detailed to serve, and are now on duty, in connection with the consulates at various foreign ports and from them all necessary information is received relative to the sanitary condition of vessels, cargoes, crews and passengers about to depart for the United States

By this means the ordinary consular bill of health is made to be a certificate of actual observation by a responsible officer whose sole duty is to aid in the prevention of the introduction of contagious diseases into the United States

Under these new laws and regulations, Surgeon-General Wyman instituted an inspection of all state and local quarantines, requiring them to conform to the standard of the Treasury Department Many of these state and local quarantines have since been transferred to the service, and the remainder have, under federal supervision, enforced regulations, affording adequate protection to the country

During the administration of Surgeon-General Wyman, the public-health work of the service has increased rapidly not only in the duties of national quarantine, but in other directions

By the immigration act passed in 1891, and also by the subsequent immigration acts of 1893 and 1903, all incoming aliens must be examined physically by medical officers of the United States Public Health and Marine-Hospital Service The importance of this duty from the standpoint of public health can scarcely be overestimated It is essentially a public-health function and properly performed excludes a class of aliens which, if admitted would be not only detrimental but dangerous

On March 12, 1896, the chairman of the Committee on the Merchant Marine and Fisheries forwarded to the Secretary of the Treasury a letter inclosing schedules of provisions for seamen, in bills then pending, and requested that they be referred to the Surgeon-General of the Marine-Hospital Service for his opinion and suggestions for their amendment.

In accordance with this request, the surgeon general convened a board to prepare a proper schedule or scale of provisions to be allowed and served out to crews of merchant vessels during the voyage. With a few minor changes Congress accepted the schedule, and it was enacted into law. The measure protects the merchant sailor while on long voyages by compelling masters to furnish him with proper and sufficient food.

The act further requires that "the foregoing scale of provisions shall be inserted in every article of agreement and shall not be reduced by any contract, except as above, and a copy of the same shall be posted in a conspicuous place in the galley and in the forecastle of each vessel," and provides for a survey by three persons, one of whom, if possible, shall be a medical officer of the Marine-Hospital Service, to pass on the provisions furnished when complaint is made, as provided for by the act.

Surgeon-General Wyman, early in his administration, pointed out the perennial peril to which the United States was subjected because of the continued prevalence of yellow fever in Habana, due to remediable causes. He suggested in his annual report for 1896 that an effort be made through diplomatic channels to induce the Spanish government to cleanse Habana. The suggestion was acted on by the Department of State, and Secretary Olney, in his letter to the Spanish minister at Washington, plainly set forth the insanitary condition of Habana and the anxiety it caused the United States. The Spanish authorities did little or nothing, however, and the sanitary regeneration of Habana was not accomplished until American occupation of the island several years later. The surgeon general did not confine his efforts to Habana alone, but maintained that all nations possessed certain international obligations in preventing the spread of epidemic disease from their seaports to the ports of foreign countries, and this idea of international co-operation in the sanitation of seaport cities he has never relinquished.

In an article published in the *Forum*, February, 1899, Surgeon-General Wyman thus expresses his views on international co-operation for the prevention of epidemic disease:

> There is little doubt that with American predominance in the island of Cuba the dreaded scourge of yellow fever will be suppressed and will in course of time almost, if not entirely, disappear. But a still further advance should be made. That great pestilential center Havana, even if purified and freed from yellow fever infection, will still be subject to reinfection from other ports in Central and South America, which are in almost as bad a condition. It is therefore worth serious consideration whether anything less than the total elimination of yellow fever from the American continents should be attempted, and it should be remembered that this disease is practically limited to the western hemisphere. . . .
>
> It is not pure optimism to suppose that an international sentiment may be awakened which will cause yellow fever in a given port, and the faulty sanitation which it implies, to be an opprobrium on the government in possession of the offending port. Every nation should be held responsible for conditions within its borders or dependencies tending to propagate epidemic diseases and to threaten other nations with which it expects to maintain a friendly commerce. As soon as the cities of our own dependencies are freed from fever by sanitation, it would be appropriate for this government to invite in convention representatives of each of the other American republics, the convention to be composed of public sanitarians, civil engineers and financiers, whose duty it should be to prepare a treaty providing for the examination of the chief yellow fever ports by a commission representing the republics concerned. Each country should obligate itself to put into effect the measures recommended by this commission, or measures of its own which would meet with the commission's approval.

In accordance with his views, Surgeon-General Wyman, in 1901, submitted to the International Conference of American States, held in Mexico, a provisional plan for international sanitation of cities.

This plan had for its object the elimination of yellow fever from seaport cities or towns which are or have been endemic habitats of yellow fever or which are liable to become foci by reason of geographical situation, commercial relations or bad sanitary conditions. The remedial measures suggested involved the subjects of sanitary improvement of harbors, sewerage, soil drainage, paving and elimination of infection from buildings.

The plan also recommended the formation of an international sanitary commission, to consist of five members, no two of whom should be residents or citizens of the same republic. They were to be appointed by the Bureau of American Republics and serve one year, when they might be reappointed or new members selected to succeed them.

The conference foresaw that by uniform application of modern sanitary methods to the seaport cities of this continent, as suggested in the surgeon general's plan, quarantine restrictions could be reduced to a minimum or totally abolished.

The resolutions, as finally adopted by the Conference of the American States, while they did not embody the surgeon general's plan in its entirety, were largely based thereon, and went far enough toward the ideal set forth to greatly encourage sanitary improvement in seaports which are a menace to the health of other countries.

The conference provided for the assembling of a convention of representatives from the health authorities of the various republics, as well as for the creation of an International Sanitary Bureau, with permanent headquarters at Washington, to encourage and carry out the measures of the general convention.

The result of the First International Sanitary Convention, which was held in Washington in December, 1902, was to secure co-operation between the various republics of the Western Hemisphere in the work of cleansing seaports and concerted effort toward the eradication of epidemic diseases. The convention recognized the interest and initiative displayed by Surgeon-General Wyman by electing him president, which carried with it the chairmanship of the International Sanitary Bureau which was organized at the same meeting.

This bureau promises to become a potent factor in the maritime sanitation of the future, and Congress, at its last session, appropriated a sum of money to cover the United States' quota of the fund for its maintenance.

As indicated in the foregoing historic sketch, the Marine-Hospital Service had for years exercised the powers, performed the duties, and carried successfully the responsibilities of a public-health service. It had suppressed epidemics, rigidly carried out the physical requirements of the inspection of immigrants, maintained an efficient system of national quarantine at all points of danger, enforced quarantine regulations in domestic insular and foreign ports published weekly sanitary reports and statistics from all parts of the world and conducted scientific investigations of epidemic diseases. In 1902 Congress determined to make the service in name what it had been in reality for years—the Public Health Service of the United States—and accordingly enacted (into law) a bill To increase the efficiency and change the name of the United States Marine-Hospital Service.

This act of 1902 was the first legislation directed toward securing harmonious co-operation between the national and state health authorities. The necessity of such co-operation had long been recognized and desired but was difficult of achievement by reason of our republican form of government. It had been difficult for the National Government to extend its operations within the borders of a state without appearing to infringe on the prerogatives of that state and it had been equally difficult for the states individually or collectively to seek aid from the Federal Government without appearing to surrender authority reserved to them by the National Constitution. During the century of development in which the Marine-Hospital Service became in reality the Public Health Service of the United States the state health organizations had also developed and improved and a sentiment of respect one for the other had been established replacing the old feeling of distrust and opposition.

The law of 1902 not only confirmed the Marine-Hospital Service as the National Public Health Service but also provided a plan for the utilization of both national and state health authorities in effective co-operation.

Section 1 provides that in future the service shall be known as the Public Health and Marine Hospital Service of the United States. Section 3 provides that medical officers in charge of the bureau divisions of marine hospitals and relief, domestic quarantine foreign and insular quarantine personnel and accounts sanitary reports and statistics and scientific research shall be while thus serving assistant surgeons general.

Section 4 authorizes the President to utilize the Public Health and Marine Hospital Service in times of threatened or actual war to such extent and in such manner as shall in his judgment promote the public interest without, however in any wise impairing the efficiency of the service for the purposes for which the same was created and is maintained.

Section 5 provides that "There shall be an advisory board for the Hygienic Laboratory provided by the act of Congress approved March 3, 1901 for consultation with the Surgeon General of the Public Health and Marine Hospital Service relative to the investigations to be inaugurated and the methods of conducting the same, in said laboratory. Said board shall consist of three competent experts, to be detailed from the Army the Navy and the Bureau of Animal Industry by the Surgeon General of the Army, the Surgeon General of the Navy and the Secretary of Agriculture respectively which experts with the director of said laboratory, shall be ex officio members of the board and serve without additional compensation. Five other members of said board shall be appointed by the Surgeon General of the Public Health and Marine-Hospital Service with the approval of the Secretary of the Treasury who shall be skilled in laboratory work in its relation to the public health, and not in the regular employment of the government.

Section 7 provides that "When, in the opinion of the Surgeon General of the Public Health and Marine-Hospital Service of the United States, the interests of the public health would be promoted by a conference of said service with state or territorial boards of health, quarantine authorities, or state health officers the District of Columbia included he may invite as many of said health and quarantine authorities as he deems necessary or proper to send delegates not more than one from each state or territory and District of Columbia to said conference *Provided*, That an annual conference of the health authorities of all the states and territories and the District of Columbia shall be called, each of said states, territories and the District of Columbia, to be entitled to one delegate, *And provided further*, That it shall be the duty of the said Surgeon General to call a conference on the application of not less than five state or territorial boards of health, quarantine authorities, or state health officers, each of said states and territories joining in such request to be represented by one delegate."

This act authorized the surgeon general to prepare and distribute suitable and necessary forms for the collection and compilation of mortality, morbidity and vital statistics. It also authorized the President to prescribe rules for the conduct of the service, and regulations respecting its internal administration, discipline, and uniform officers and employes.

The conferences called for by this act are very valuable in preventing the spread of epidemic diseases by insuring co-operation of state authorities with the Public Health and Marine-Hospital Service. Matters of sanitary interest, ventilation, housing, disposal of garbage etc, and matters relating to prevention of epidemic diseases are considered by special committees appointed by the surgeon general for that purpose.

The state health authorities are thus brought into close relationship with the Public Health and Marine-Hospital Service. The municipal health officers, through their dealings with the state boards of health, form a part of the system. The result is an interchange of views and mutual understanding between all health authorities, and the closer relations thus established will be of great benefit in the public-health work of the future.

An act to regulate the sale of viruses serums, toxins, and analogous products, and interstate traffic in such products, approved July 1 1902, imposed additional public-health duties on the service. The regulations formulated and promulgated by authority of this act provide for the inspection of all establishments engaged in the manufacture of serums, vaccines, etc, by officers of the Public Health and Marine-Hospital Service. The inspectors are required to visit, unannounced, the various establishments, and make a report on the methods employed and conditions existing in these concerns. Licenses are granted or refused, according to the recommendations of the inspectors.

The administration of Surgeon-General Wyman, aside from the great expansion of the public-health work of the service, has been characterized by marked improvement in methods of bureau administration and station inspection. This result has been effected by revised regulations, by reorganization of the bureau, and by more systematic inspections and reports of all classes of stations. These inspections extend to the fifty vessels employed in quarantine work—steamers barges and launches.

TRAVEL NOTES

V

ITALY AND THE GREAT ANTIMALARIAL CAMPAIGN

LEWELLYS F BARKER MD

CHICAGO

BERLIN, June 25 1904

In Italy and Sicily as in Spain, the medical traveler is prone to pay more attention to, and profit more from the history and art of the land than its medicine. And this with right the key to the history of Europe is to be sought in Rome and who would know Rome must study Sicily. And yet the physician traveling in Italy, who gave himself over entirely to the satisfaction of his historical and esthetic inclinations, would miss much, for Italy has recently been making great strides forward commercially, socially and scientifically Especially is this true of northern Italy, which presents a marked contrast to the southern regions where poverty depresses, begging still annoys and dishonesty yet exasperates the American traveler That the country is everywhere and in almost all particulars making a swing upward is obvious The national credit is much improved, as the traveler finds almost to his sorrow when he compares the number of lire he now receives in exchange for a pound with the larger amount dealt out to him a few years ago

The aquarium at Naples is visited by everyone who goes to the city, and the traveling physician, above all should not miss seeing it. This mother of marine laboratories, superbly situated in the middle of the Villa Nazionale, is still presided over by its generous founder Dr Dohrn, and the work on the morphology and physiology of the animals of the Mediterranean is being more actively prosecuted than ever Tables are supported by Prussia Saxony, Bavaria, Württemberg Baden Hessen, Hamburg Italy, Austria Hungary, Russia, Holland Belgium, Switzerland the Universities of Oxford and Cambridge the British Association for the Advancement of Science the Smithsonian Institution and the Carnegie Institution in Washington Many American biologists have profited by the magnificent facilities afforded there, and the Zoological Station at Naples has undoubtedly had a great influence on the development of our excellent seaside laboratories in America The well known conservator of the institution Lobianco makes exquisite preparations which are sent to zoologic museums in all parts of the world The station has its own steam yacht a steam launch, and many sailing boats and rowboats for the collection of material Many of the fishermen have long been associated with scientific collectors As we went through the laboratory Dr Dohrn pointed out to us one elderly Neapolitan who formerly collected for Johannes Müller

The example set by Dr Dohrn as an organizer and leader of a laboratory must interest everyone engaged in executive work It is a part of his policy to permit the greatest possible freedom of investigation and publication to those who study there He is ever ready to give advice and to assist where he can and in some instances perhaps to lead but he never attempts to drive, nor does he make an effort to direct the work too much along the lines of his own interests in research Two men may publish from the laboratory results quite contradictory to one another if they wish to do so, the director exercises no censorship which would prevent this, for time he thinks, will best decide the merits in any given case. And it might be better, in the long run, if this policy were always followed by the heads of research institutions A new physiologic department of the Zoologic station is being built, it is hinted that great attention is to be paid in the near future to physiologic chemical researches in this department

At the head of the Royal University of Naples this year is the distinguished psychiatrist, Leonardo Bianchi, well known to American neurologists on account of his views regarding the functions of the frontal lobes The university is visited by more than 5 000 students yearly, has all four faculties of which the medical faculty is by far the largest Of the medical teachers besides Professor Bianchi may be mentioned Pianese, Rho, Pasquale and Biondi as those whose names are best known to us in America

I must confess to having been much surprised at the number and size of the universities in Sicily The Royal University in Palermo has 1,400 students, the University of Catania 1,060 and the University of Messina 645 Among the professors and instructors are a number of men well known to readers of anatomic and pathologic literature, e g, Sanfelice (hygiene) and Fusari (histology) in Messina, Petrone (pathologic anatomy), Ughetti (general pathology), d'Abundo (psychiatry) and Staderini (anatomy) in Catania, and Marcacci (physiology), Trambusti (general pathology), Acquisto (histology) and Mirto (psychiatry) in Palermo

One of the interesting sights to the medical man in Palermo is the remarkable osteologic collection presented by the catacombs of the Convento de' Cappuccini In the subterranean passages beneath the convent the mummified bodies of the wealthier inhabitants of Palermo were stored for decades until a few years ago, when the government put a stop to this method of disposal of the dead A curious custom was, in the later years, associated with the practice, the photograph of the living individual was placed in the catacombs beside the remains This juxtaposition tempts to comparison, indeed, I can see no other reason for placing the photographs there Sometimes the photograph impressed us most, sometimes, a gentleman with us thought he rather preferred the appearance of the skeleton! The only recent interment in the catacombs is that of the body of Signor Crispi, and for this special permission had to be obtained His widow, I was told, repairs at regular intervals to the subconventual regions to remourn her dead

In Rome one's medical interest naturally centers in those Italian investigators who have done so much to clear up the clinical history, pathology and epidemiology of malaria, Marchiafava Celli, Bignami and Bastianelli These men are all members of the Medico Chirurgical faculty of the Regia Università degli Studi, Marchiafava being professor of pathologic anatomy Celli professor of hygiene, Bignami professor of general pathology, while Bastianelli is in clinical work It must be admitted, I think, that the credit for the greatest Italian work on malaria belongs, not to a Roman, but to the Pavian, Camillo Golgi, but, in spite of this, the Romans have made and are still making contributions of high importance to the subject The advances due to the Italians have been so thoroughly presented to American readers by American investigators of the malarial diseases that it would be superfluous to refer to them here

One feature, perhaps, may be mentioned, namely, the foundation and activity of a special society for the study of malaria This society dates from 1898 and is due to the initiative of Fortunato, Franchetti and Celli The date of foundation was propitious Ross had just made his important observations on the relation of mosquitoes to malaria in India, Ficalbi had studied the species of mosquitoes and their habits in Italy, Golgi in Pavia, and Marchiafava in Rome, had perfected the clinical study of the blood in the various forms of human malaria and Grassi had observed the species of mosquitoes most prevalent in malarial districts and had regarded the *Anopheles* as the most suspicious variety In the following autumn Bastianelli, Bignami and Grassi brought the direct proof of the propagation of human malaria by the mosquito and confirmed Ross' work regarding the *Anopheles* The Society for the Study of Malaria undertook to draw important conclusions from this well confirmed theory of malarial transmission and to apply these in the best possible hygienic manner The work began in a modest way on a farm now famous, known as *la Cervelletta,* Celli in 1899 established there the first station for the study of malaria in the Roman *Campagna* Since then more than a dozen stations have been established under competent direction, in the various parts of Italy where malarial fevers prevail, and though the material resources of the society have been small the energy, activity and personal sacrifice of the scientists who have been engaged in the investigations have been great and a rich treasure of epidemiological and prophylactic facts has been accumulated *

On the epidemiologic side the society has made exhaustive studies of the geographical distribution of the various types of malarial fever, of the times of year when each type is most prevalent, of the relation of *recidives* to the outbreak of new epidemics, of the places and times, where the *Anopheles* are abundant and malaria is not epidemic, of the relations of rice growing to malaria and of a number of other questions

Still more important and extensive have been the researches on the prophylaxis of malaria. These included attempts to destroy mosquitoes and efforts at seroprophylaxis, but the most practical results in Italy have been obtained first by prophy lactic dosing with quinin and second by mechanical protection against mosquito bites. Of nearly 1,000 people treated daily in 1902 with quinin only 1.5 per cent were attacked, while from 14 to 85 per cent of the people untreated in the same districts developed malaria. More than 2,000 people were given a prophylactic dose of 5 grams once every week or ten days, of these some 10 per cent developed malaria while 48 to 80 per cent of those untreated developed the disease. The quotidian prophylactic dose is more protective therefore than the weekly single dose. No special harm seemed to follow the daily dosage. Further the prophylactic use of quinin even when unsuccessful in preventing an attack of malaria (though this is rare) does not hinder at all as some have believed but rather facilitates the therapeutic action of larger doses of the salt. The larger curative doses far from being less efficacious for individuals who have received prophylactic doses arrest more quickly the fevers which sometimes develop in spite of the prophylactic measures undertaken. The Italian experiences are strongly in favor, too of the use of hydrochlorate and bichlorhydrate of quinin as a preventive rather than the more highly vaunted but less effective mixtures of iron arsenic and quinin.

---

*A report on the work from 1898 to 1903 was made by Celli at the Hygienic Congress in Brussels and published in the Arch Ital de Biol vol xxxiv 1903 p 3

Much has been done by the society in the way of educating physicians how to use quinin properly. Physicians are urged in dealing with malaria not to be satisfied with giving the small number of doses which cut the attack short in those who have acute manifestations of the disease but emphasis is laid on the following points:

1. During the months when malaria prevails and when one can not count on the security of mechanical protection from mosquito bites or other prophylactic methods the preventive treatment of healthy persons and of those in whom latent infection is possible should be resorted to. The daily or weekly distribution of quinin is not difficult in the form of sugar-coated tablets, the cost of the prophylactic treatment is not great (quinin is sold by the Italian government) two or three francs per head for the whole season of four months. The quantity of quinin necessary for each person in the course of the whole prophylaxis is less than that which is often necessary to use to completely cure a fever once contracted.

2. In those rare instances, where in spite of prophylaxis malarial fever develops it is necessary to administer at once large therapeutic doses to cut short the attack and to continue this stronger treatment *for from two to four weeks* before resuming again the smaller prophylactic doses.

3. For individuals in whom recurrent attacks are obstinately repeated in spite of preventive treatment an intense therapeutic treatment (gr. 0.50 to 1) should be begun and followed from four to six weeks; if necessary in such cases a reconstructive treatment with iron and arsenic is recommended in association with the quinin therapy.

Nothing is said in the epitome of the report of the society with regard to the simultaneous prevalence of malaria and typhoid fever. In view of our experiences in America the question might well be asked "Are not some of the *obstinate* malarial fevers described by the Italians really typhoid?" Typhoid fever is a disease much more poorly understood in Europe than in America. It is conceivable that a systematic study of 'resistant' malarias in Italy with the aid of the Gruber-Widal reaction might be of value.

Mechanical protection against mosquito bites has yielded marvelous results in the prevention of malarial infection wherever it has been tried. In 1901 on the initiative and with the aid or counsel of the Italian society 5,165 persons were mechanically protected against malarial fever. In badly malarial localities of 4,363 individuals carefully protected 1.9 per cent only were attacked with primary malarial fever while of 802 less well protected an average of 10.9 per cent became sick. In 1902 of 5,851 mechanically protected there were only 2.8 per cent of new infections and only 10.1 per cent of recidives. In this way a large number of poor families which for years had suffered from malarial fever were, as Celli puts it, reborn to a new life thanks to mechanical prophylaxis either alone or, where necessary, associated with the treatment of recidives. Unfortunately this mechanical prophylaxis is relatively expensive and is, therefore, applicable only to a limited class such as railroad employes and the like, it is beyond the means of the Italian peasant, for whom the quinin prophylaxis is alone available.

Italy, thanks largely to the efforts of members of the society, is the first country that has established special anti-malarial legislation. The Italian parliament has passed two laws. According to the first, it is possible to buy pure quinin cheap in every part of Italy, the sale being controlled by the government; according to the second, quinin must be furnished *gratuitously* and *abundantly* by physicians to workmen and to peasants at the expense of their employers. In case a workman contracts malaria while in service through culpable withholding of quinin a suit for damages is well grounded.

The state is setting a good example by giving its own employes on railroads and in custom houses properly protected dwellings. The revenues from the sale of quinin (it is estimated that it will amount to 30,000 kilograms yearly), though the alkaloid is furnished at a very low price will, it is believed, be considerable; they are to be devoted solely to the service of the national struggle against the secular enemy, malaria. When it is realized that 4,000,000 hectares of Italian soil are uncultivated solely on account of the dangers of malaria, and when it is recalled that 2,000,000 Italians are annually attacked by the disease, and that from 12,000 to 15,000 die each year therefrom, the social and economic importance of the anti-malarial campaign becomes obvious. It is in many ways, as Fortunato has emphasized and as Celli repeats in his report, the essential problem for Italy and plays a capital rôle in the urgent and menacing meridional question.

At the ancient hospital of Santo Spirito early one morning I found both Bignami and Bastinelli making morning rounds. The old hospital is most interesting historically, but scarcely suitable for modern work. Founded as long ago as 1198 by Innocent III, it has been added to and remodeled from time to time. It contains an enormous number of beds for medical and surgical patients and has connected with it a lunatic asylum and a foundling hospital. The physicians in charge lament the antiquity of the arrangements, but are buoyant in the hope that a new hospital, with all modern improvements, is soon to be provided.

Though the Roman hospitals are old, many of the scientific institutes are modern. Thus Bignami has just gotten settled in a new laboratory, which though not large, is well arranged and looks active. Now that the stress of the malarial work is over, Bignami is turning his attention more particularly to the pathology of the central nervous system, and I spent an interesting morning examining some of his newer preparations. Among other specimens he showed me sections of the horn of Ammon from hydrophobia material in which the bodies described and believed by Negri to be the parasite of rabies were exquisitely demonstrated. The bodies are relatively large, situated in the protoplasm of the nerve cell body, and are sharply differentiable by staining methods; it is curious that they went so long overlooked. They occur in the nerve cells in different parts of the central system, e. g., in the anterior horn cells of the spinal cord, in the large cells of the formatio reticularis and in the Purkinje cells of the cerebellum but they are most abundant in the cells of Ammon's horn. Certainly they look like parasites; they are quite different in appearance from the ordinary cell inclusions and cell degenerations with which pathologic histologists are familiar. The fact that the hydrophobia virus under certain circumstances passes through the Berkefeld filter does not necessarily exclude the Negri bodies from being the causal parasites of hydrophobia, for while the bodies described by Negri are much too large to pass through the filter, it is easily conceivable, as Celli and de Blasi suggest, that in the protozoan cycle forms much smaller than the larger bodies of Negri may occur.

URIC ACID THEORIES

An interesting example of the persistence of a theory that for all practical purposes has seen its rise and fall, *is furnished by the case of uric acid.* No *matter* how abundantly the results of reliable research are published, nor how carefully the leading clinicians controvert the mistaken ideas of a previous generation a large proportion of the unprogressive will cling to the most worn-out theory or system for no better reason than that the idea once secured a firm place in their mental armamentarium and that it would require an effort to dislodge it. A student is told that uric acid accumulates in the blood and leads to all sorts of diseases, and that uric acid in the urine means an excess of uric acid in the blood; if he is of a certain type for the rest of his life a brick dust deposit in a urinal calls for sodium salicylate or some other favorite remedy, and never for a moment will he imagine any room for question of the absolutism of the uric-acid doctrine. Furthermore, as Billings has said the theory which was accepted at one period by the medical profession becomes at a later period the theory and property of the laity. And thus many manufacturers of patent or proprietary remedies wax rich selling a "solvent" which does not dissolve a substance that does not accumulate in the "system" and does not cause a host of ills.

The widespread acceptance in this country of the supreme importance of uric acid as a cause of most of the diseases that flesh is heir to, is probably due more to the writings of Haig than to any other one cause. Using methods that are known to be unreliable he secured data that *can not be corroborated* and with these as a basis followed out a marvelous train of logic to the ultimate conclusion that practically all disease is due to uric acid, and that a vegetable *diet* is a guarantee against the sufferings of mortal man. No advance in physiologic chemistry and pathology, no amount of refutation *of his claims, seems to have interested or* swerved him in the least, for in his newly published "Epitome" on uric acid[1] he ignores everything but his own cherished beliefs and calmly follows them as they lead to the conclusion that appendicitis consumption and uterine fibroids are all expressions of the pernicious effects of uric acid, and in turn to meat eating. We have been reading this book, and psychologically it is one of the most interesting things of the kind recently published.

The fundamental ideas, as Haig gives them, are that uric acid is deposited in the tissues of the body when the solvent power of the blood is reduced, and taken up in the circulation when the solvent power of the blood is increased, whether *by diet or drugs.* The result in the first case is local inflammation of the fibrous tissues, leading to such conditions as appendicitis, uter*ine fibroids, catarrh, pneumonia, phthisis, cirrhosis,* and even to liver abscess. Bad as this is the results that follow the dissolving of uric acid and its circulation in the blood are ever so much worse for Haig says uric acid forms a colloid which blocks up all the capillaries, and naturally as a result the various organs do not get *enough nourishment* and the heart has a terrible time trying to push the slimy uric acid through the capillaries. Nothing could be simpler. And all this being true (?), it is easy to see how we have produced headache epilepsy, insanity, fatigue paralysis dilated stomach diabetes, Bright's disease boils, aneurism, leukemia, pernicious anemia, exophthalmic goiter and piles. This is no joke—these are only a few from the list that fills over three solid pages of the epitome.

But we wonder how the oculists will look on the statement that migraine is due to the presence of uric acid in the blood. Dr. Haig also has cured hundreds of cases, but without a single lens. And what is the poor lay brother to do about it? Shall he live on excelsior breakfast food and Battle Creek products or ought he to visit a refractionist and get a new pair of glasses? Possibly the homeopathist will offer the helpful suggestion that right-sided migraine comes from eyestrain and left-sided from uric acid or *vice versa.* At any rate, the speed and endurance of the hobby horse is demonstrated.

We pay this much attention to Haig's book largely because at one time his name assumed prominence as authority on uric acid as a cause of disease owing to the fact that at that time our methods of research had not developed sufficiently to afford any accurate knowledge of the facts in the case. Many physicians have Haig's books on their shelves and have been much influenced by them in their practice. *It will be readily granted* that the advice as to diet hygiene and therapy recommended on the basis of this theory, has often been productive of excellent results, *and probably* seldom if ever harmful, but real progress can not be made on a basis of error, and it is necessary to appreciate the fallacy of much of the talk *concerning uric acid.*

We have not space to go into the reasons involved in the objections to this theory but our readers can secure first-hand information from available sources in the English language.[2] Billings has tersely summed up the results of our studies in the following words: "Some of the fallacies of uric acid are therefore: 1. That uric acid is toxic; 2, that it is a causative factor of any disease except gout 3 that uricacidemia meaning acid blood does exist 4, that the chemical reaction of the blood may be altered by the medicinal quantities of the alkalies or by diet 5, that uratic deposits may be dissolved out by the administration of alkalies, 6 that lithia is a uric-acid solvent of unusual potency 7 that uric acid is an abnormal constituent of the urine 8 that an excess of uric acid in the urine at any one time or a deficiency at another time indicates an abnormal condition in reference to uric acid 9 that rheumatism is due to uric acid."

---

SPECIALISM AND SCIENTIFIC SUCCESS

A very general impression prevails at the present time that success in scientific investigation can only be hoped for from those who are highly specialized students of their branch. All departments of science are popularly considered at least to have developed to such an extreme of refinement that only the specialist can hope to make the distinct advances which add to our present knowledge. Every now and then there comes a distinct contradiction of this idea that is worth while noting. After all, it must not be forgotten that after the cause of infectious disease had been for so long a subject of study on the part of physicians and when presumably only from a physician could the solution of the mystery of disease etiology be looked for, Pasteur, a chemist and biologist, stepped in and the riddle was solved.

At the present moment some of the most interesting work that is being done in progressive medicine is that of Professor Arrhenius the distinguished scientist to whom we owe the foundation of the science of physical chemistry. The Swedish professor is now engaged in investigating the physical chemistry of serums with the idea of making our knowledge of these complex substances more definite so as to enable us to appreciate the real reasons for their action and the sources of their energy. It seems not unlikely that the ionic theory of the constitution of matter and the electro-chemical factors which have been found so important in solutions may serve to broaden the field of application of serums and even secure the discovery of further curative agents of this kind.

Arrhenius is perhaps the most interesting type of the successful non-specialist scientist now alive. He received the Nobel prize for his successful investigations in physical chemistry before he was 45 yet his scientific work ranges, as a writer in the *Popular Science Monthly* said not long since, "from salt solutions to comets and their perihelion periods to the typhoid bacillus." His record lends little support to the belief that a scientific man must be a narrow specialist if he is to attain eminence. This belief rests on a misapprehension. It is true that scientific men are accumulating facts at a tremendous rate and that this apparently makes it more and more difficult for any one man to be master of anything more than a small branch of a single science. Along with this accumulation of isolated facts, however, there goes the development of simplifying generalizations or laws which enable men to grasp and remember an enormous number of facts. The smaller mind is apt to be so weighed down by mere accumulation of facts as not to be able to see the great laws which they demonstrate. It is a case of not being able to see the trees because of the leaves.

There would even seem to be in such cases something more than a hint that the modern methods of education which insist to such a degree on cumulative information may prove in many ways to be a mistake. Scholars with possibilities of original work in them become so loaded down with the supposed results of others' observations and with the uncertainties of elaborate technic that they are never brought really face to face with the important problems to be solved. Direct observation is the only method of broadening the field of knowledge that has ever given satisfactory results. Elaborate theories have been popular, but they usually delay the progress of science. For observation what is needed is the faculty which John Ruskin once declared to be the rarest quality of the human mind that namely of seeing things as they are and telling them simply as they appear. There is always room for the simple observer in medical science, and never more so than at the present moment.

POPULAR MUSEUMS OF HYGIENE AND DISEASE

In all large cities we find various kinds of museums and collections for the instruction and amusement of the people, but there is one form of museum or permanent exhibition still almost without representation on the long list of these useful institutions, namely, popular museums of hygiene and knowledge of disease. The usefulness of museums of this kind in promotion of knowledge in regard to subjects of such importance as health and disease is so self-evident that no special argumentation is required. Medical men especially appreciate the unsurpassed value of the eye for the conveyance in teaching of strong, living and hence lasting impression. This is the era of publicity in medicine, secrecy is only the stamp of charlatanism successful prevention of many diseases, e g, tuberculosis must ever depend in large measure on the knowledge among the masses in regard to such diseases.

There are few diseases that lend themselves so well for illustration by museum methods as tuberculosis the one disease above all others to be stamped down. The temporary exhibit in Baltimore last winter and the permanent tuberculosis museum in Berlin show well enough how much may be accomplished in a short time and with relatively small expense. The extent distribution and death rate of the disease may be shown by maps, tables and curves. The bacillus may be demonstrated in drawings cultures and microscopic preparations, and the effects of tuberculosis on the body of man and of animals by means of anatomic preparations by the side of which specimens of normal organs would serve for purposes of comparison Preventive means, such as apparatus for ventilation and disinfection sputum cups, and the like, would form interesting exhibits when arranged along developmental lines The construction of tents, of sanatoria, of healthy homes, healthy factories, etc are other fields for illustration Portraits and busts of the founders of our knowledge of tuberculosis and a collection of the classical literature of tuberculosis would most fittingly be found in this museum all arranged in the attractive manner that curators so well understand Fancy the interest the reverence with which the father and mother would study such a collection when it became known that some one of their children were showing signs of early tuberculosis! We unhesitatingly recommend to our associations against tuberculosis this plan, which no longer is a new idea, of permanent, popular museums of tuberculosis No doubt much good would come from co-operation in various ways

Practically all communicable diseases are susceptible of similar treatment In their last report to the House of Delegates the Committee on Venereal Diseases state that the next step in their prevention is publicity and education Wisely managed, much valuable information in regard to these infections could be conveyed by museum methods

There is consequently a large field for popular museums of the kind indicated which becomes still more extensive if such museums attempt to cover also general hygiene a subject that in this country as yet is almost wholly without museum representation even for more purely technical and educational purposes Taking it all in all, we must conclude that the time has come when endowments and appropriations are needed for museums of hygiene and disease just as well as for archeology, anthropology, zoology, art, and the like

THE CAUSES OF THE CACHEXIA ACCOMPANYING MALIGNANT TUMORS

The underlying causes of the anemia and malnutrition which accompany the development of malignant new growths and which we speak of as cachexia have been, to some extent, obscure It is easy to understand why a patient with a large extensively ulcerated growth infected as this is bound to be, should suffer from anemia and malnutrition, the absorption of septic material sufficing to explain this It is a well-recognized fact that small non-ulcerated neoplasms can also give rise to well-marked cachexia, even when there are no signs of sepsis The cachexia in these cases has been explained as due to the absorption of toxic substances secreted by the tumor cells, but so far no one has attempted to explain the nature of the toxins Recently, Kullmann[1] has made some interesting experiments which seem to clear the matter up He finds that carcinoma cells contain a substance which has a strong solvent effect on blood corpuscles When added to blood outside of the body, or when introduced into the bodies of animals, this substance produces a prompt and active dissolution of the red blood corpuscles The substance could be distinguished from the hemolytic substance normally found in all tissues, and was much more powerful than this Kullmann cites other authors to show that a similar substance has lately been isolated from sarcoma cells The theory seems very plausible

THE ACTION OF SALICYLATES ON THE URINARY TRACT

The salicylates have been so widely employed and have proved of such distinct utility in the treatment of a large number of disorders that the fact should not be ignored that they may give rise to irritation of the urinary tract, particularly the kidneys Some observers have even reported the occurrence of nephritis and desquamative catarrh of the urinary passages from this cause In order to convince themselves of the accuracy or otherwise o statements of this character, Dr Carl Klieneberger and Dr Richard Oxenius[1] made a careful study of the urine from a large number of practically normal persons and from individuals suffering from rheumatic disorders particularly polyarthritis, to whom later salicylates were administered As a result of their observations they found that the administration of even small doses of salicylates gave rise to the urinary but not to other clinical phenomena of nephritis and also of desquamative catarrh of the entire urinary tract, but that these dis p peared with the continued administration of the medicament Habituation to the drug did not appear to develop as similar symptoms reappeared when the administration was resumed after an interval of a few days omission It appeared that a toxic or febrile nephritis is present in the majority of cases of febrile rheumatic disease and that this subsides under the use of salicylates On the other hand the salicylates themselves give rise to a characteristic form of nephritis, from which recovery takes place as a result of their continued administration

THE ETIOLOGY OF SCURVY

Although the symptomatology of scurvy differs somewhat as the disease occurs in adults and in children prevention and cure can be effected in both apparently by the observance of certain dietetic regulations While this fact has long been appreciated, the factors on which the disorder actually depends have never been clearly made out The common belief is that the deterioration of the tissues that is the most conspicuous feature of the affection is due to the absence from the food of certain chemical principles contained especially in fresh vegetables but the identity of these has not been established It has also been suggested that the disease is of infectious origin, but here again the hypothetical causative micro-organism has not yet been isolated In support of this latter view, Mr Myer Coplans[2] presents certain interesting evidence, obtained in the Transvaal toward the close of the Boer war and subsequently In general, this is to the effect that the disease occurred not in those deprived of any particular article of food, but among those provided with the same diet whose surroundings, however were of a character conducive to infection Further the best therapeutic results were obtained in those cases in which attention was directed to disinfection of the mouth in addition to constitutional treatment The disease began as an inflammation of the mouth the general symptoms following at varying intervals Improvement or the reverse took place in direct relation to the improvement or aggravation in the condition of the gums The treatment consisted of rest in the open air and isolation from previous surroundings together with rigorous and frequent antisepsis of the mouth

HEALED MILIARY TUBERCULOSIS OF THE LUNGS

The possibility of healing tuberculous lesions is well established Instances of healed or healing local pulmonary glandular osseous and synovial tuberculosis are very common The frequency with which healed tuberculous areas are encountered at postmortem examination is generally known But even more extensive tuberculous outbreaks such as tuberculous peritonitis pleuritis and even leptomeningitis may heal completely Instances of healed miliary tuberculosis however must be very rare Spengler[1] reports recently a case of healed miliary tuberculosis of the lungs in a man who first came under observation in 1889 when both apices showed evidences of involvement In the following year there were signs of extensive invasion of the rest of the lungs He was treated with tuberculin on several occasions until in 1894 when bacilli disappeared from the sputum the temperature remained normal and the physical signs indicated retrogression of the pulmonary lesions A laryngeal tuberculous ulcer which had appeared in 1893 also healed Death occurred in December 1894 after an illness of four weeks, marked by cerebral symptoms Unfortunately the autopsy was limited to the lungs which showed apical adhesions, and numerous prominent hard, small nodules of pure scar tissue scattered throughout all parts of their substance Microscopically these nodules showed no bacilli no giant cells no epithelioid cells here and there were a few small necrotic foci, some fibroblasts and young vessels but otherwise only scar tissue The case is cited by Spengler as an instance of the beneficial action of tuberculin which should be given repeatedly at intervals of not longer than six months We believe that the case may be accepted as one of healed miliary tuberculosis of the lungs but that the actual influence of tuberculin in a single case like this can not be determined especially in view of the fact that the cerebral lesion in the case remains unknown, for the latter might have been of tuberculous nature

THE VALUE OF THE LEUCOCYTE COUNT IN APPENDICITIS

The significance of the changes in the white corpuscles which occur in appendicitis has of recent years been the source of a great deal of discussion, and a perusal of the proceedings of the various medical societies shows that on the one hand there are those who consider the leucocyte count of little or no value, and on the other those who perhaps pin too much faith on it The differences of opinion are so great that it seems hard to explain them Several factors are doubtless at work to cause the disagreement Among the more important of these must be mentioned the basing of opinion on an insufficient number of cases, too infrequent blood examinations and the tendency to regard the blood examination as a specific diagnostic point rather than to consider it as a link in the diagnostic chain The ground has recently been worked over by a number of observers, among whom must be mentioned Cazin and Gros,[1] Rehn and French[3] The attitude which has generally been taken with regard to the significance of a leucocytosis in appendicitis is that the degree of leucocytosis is an indication of the presence or absence of pus or of peritoneal involvement Attempts have been made by various authors to fix a boundary line so that we could say that if the leucocytes were below this arbitrary limit pus was not present if above it, pus was present The studies above mentioned show that no such arbitrary division can be made It is true that cases with a very high leucocytosis, over thirty-five thousand white cells per cubic millimeter, for example, nearly always showed pus but even this was not invariably the case Cazin and Gros in their work lay a good deal of stress on the importance of making frequent counts in a given case and observing whether the number of leucocytes tends to increase or decrease According to these observers and French corroborates them in the main, the occurrence of a gradually increasing leucocyte count is of much greater significance as regards pus formation than the mere number of the leucocytes In his series of cases French noted, on the other hand, that where the cases were tending to recovery the number of leucocytes gradually fell As regards the leucocytes in cases with general peritonitis, the remarks referring to the question of pus formation are applicable French found that 50 per cent of the cases with general peritonitis showed no leucocytosis Rehn also reports that two out of six cases with diffuse peritonitis showed a lack of leucocytosis Here again, experience shows the insufficience of single or scattered counts and the value of daily observations either a very sudden rise or less frequently a very sudden drop indicating peritoneal involvement The view which French takes of the matter after studying the literature and his own cases, is that a good deal of work remains to be done to place the significance of the leucocyte count in appendicitis on a firm basis He suggests that the differential count of the leucocytes in these cases should be worked up much more fully, as the few instances in which this has been done indicate that it may be of value The general impression gained from the papers cited is that the changes in the leucocytes may certainly be of both diagnostic and prognostic import, but that these changes must be considered in connection with the clinical aspects of the case, and that the best results will be obtained by daily and systematic examinations

Medical News.

CALIFORNIA

Hospitals—The Fresno County Hospital has been recently completed at a cost of $100,000, and has accommodation for 150 patients——Mr and Mrs James H Hough have agreed to erect a receiving hospital for Stockton at a cost of $10 000 provided the city binds itself to maintain the institution

Personal.—Dr Ray L Wilbur assistant professor of physiology in Stanford University has resigned and will take up private practice——Dr Edward P Rockhill U S Army Presidio of San Francisco who was operated on for appendicitis, has resumed his duties at the General Hospital——Dr C Van Zwalenburg Riverside, has resigned as physician of Riverside County

Accidents—Dr Winifred S Foster Oakland was severely injured in a collision between her buggy and a street car near Lorin——Dr James D Hill San Francisco was thrown to the ground from his automobile July 27, and narrowly escaped serious injury——Dr William J Hosford Alameda sustained severe injuries to his leg in a bicycle accident a few days ago——Dr James M Shannon Oakland was thrown from his buggy in a collision, his nose broken and his knees badly cut——Dr Guido E Caglieri San Francisco was recently thrown from his horse fracturing his femur

To and From Europe—Dr William I Hibbard Pasadena sailed for Germany July 23——Dr and Mrs W J Chambers Corona, are spending two months in Europe——Dr Vida Redington, Oakland is making a leisurely tour of the Eastern States and Europe——Dr and Mrs Hirschfelder San Francisco have returned from Europe——Dr Harry M Sherman San Francisco, has returned from abroad——Dr and Mrs Arthur H Mays, Sausalito, have gone to Europe——Dr William A Martin, San Francisco has returned after a stay of a year and a half in Europe——Dr Ray L Wilbur Stanford University has returned from Europe

Appointments—Dr Charles M Linsman Bieber has been appointed assistant physician of Lassen County vice Dr Arthur L Bradshaw resigned——Dr Henry J B Wright has been appointed to fill the unexpired term of Dr William D McDougall on the San Jose Board of Health——Dr Lewis A Perce Long Beach has been elected president of the State Board of Medical Examiners——Dr Stephen H Runtz has been elected president of the newly organized Placerville Board of Health——Dr Fred C Gerlach has been made secretary of the San Jose Board of Health and health officer——Dr Dennis D Crowley Oakland has been appointed district surgeon of the Santa Fe system

DISTRICT OF COLUMBIA

School Inspection—The commissioners have approved the recommendations of Dr William C Woodward health officer and the Board of Education, that amendments be made to the regulations governing the medical inspection of public schools in the District consisting of changes in the wording of the various sections the addition of more specific rules relating to diseases and various other details calculated to make more effective the operation of the regulations

ILLINOIS

Personal—Dr William Jayne, Springfield has been reappointed a member of the State Board of Public Charities

Smallpox in Zion—It is said that there are 16 cases of smallpox in Zion City and neighboring towns are taking precautions to prevent the spread of the disease

Expensive Spitting in Seneca—A new ordinance was passed by the Seneca City Council imposing a fine of not less than three nor more than twenty five dollars for any person caught spitting on the sidewalks

Physician Insane—On the application of his wife Dr Howard R Weber, Highland was taken before a court at Edwardsville, July 25 declared insane and committed to the Illinois Southern Hospital for the Insane Anna

McAllister Hospital Completed—The new McAllister Hospital, erected at Waukegan, by the generosity of the late Mrs Jane McAllister, at a cost of $21,000 was opened for public inspection August 5 The building contains 45 rooms

Hospital Addition Open.—The new $140 000 ward addition to the Illinois Western Hospital for the Insane Watertown was informally dedicated August 2 and 300 new patients from Lee Ogle and Stephenson Counties were installed The new structure increases the capacity of the institution to 1,200 patients

Illinois Not Responsible—In the final report of the investigations made regarding the complaint of St Louis, that its water supply was contaminated from Illinois sources, the State Board of Health draws the following conclusions

> 1 The water supply of St Louis is taken almost entirely from the Missouri river
>
> 2 The water of the Illinois river is so much purer than that of the Missouri that if the city of St Louis took large quantities from the Illinois river the water supply would be better than it is coming from the Missouri
>
> 3 The increased flow of Lake Michigan water in addition to the sewage coming through the drainage canal has improved the quality of the water of the Des Plaines and Illinois rivers
>
> 4 The contamination of the Illinois river through the farm and village and city drainage and sewage from commercial enterprises is probably greater than from the drainage canal under present conditions

Chicago

Fined for Selling Cocain—Dr Adolph Brendecke was fined $100 by Justice Caverly for selling cocain to minors

• **The Week's Deaths.**—Acute intestinal diseases again heads the list of deaths, with 111, violence caused 62 deaths, consumption 58 heart diseases, 41, Bright's disease 29, cancer, 22 and pneumonia 20 The total deaths were 496, equivalent to an annual death rate of 13 41 per 1 000

Smallpox—During last week eight cases of smallpox were sent to the Isolation Hospital Two of these were colored men and one was a woman 60 years old who claimed to have been vaccinated in childhood and had an imperfect scar as proof She had, however never been revaccinated and none of the others had ever been vaccinated at all

Low Mortality Among Children—The department of health makes the following comments on the lessened mortality among young children this season

> One of the most remarkable features of the present most remarkable season as to the public health is the unprecedentedly low mortality from the contagious diseases of childhood and as a consequence an unprecedentedly low general death rate for the city Only one death each from diphtheria and measles three from scarlet fever and four from whooping cough were reported during the week
>
> Since the first of the year there have been 212 deaths from diphtheria during the corresponding period of 1903 there were 328 diphtheria deaths—decrease this year more than one-third (35 3 per cent)
>
> Deaths from scarlet fever show a decrease of 52 2 per cent—241 last year 115 this year
>
> In the whooping cough mortality the decrease is 80 per cent—241 deaths in 1903, 48 in 1904
>
> Against the 23 deaths from measles since Jan 1 1904 there were 258 in the corresponding period of last year—a decrease of 91 per cent
>
> The gross mortality of the four principal contagious diseases of childhood thus far in 1904 is not much more than one-third (37 3 per cent) that of the corresponding period of 1903

INDIANA

Smallpox—Goshen has six cases of a severe type of smallpox with one death The disease was as usual diagnosed as chicken pox and no precautions were taken

On the Sick List—Dr Henry C Dixon Tunnelton, is dangerously ill following a cerebral hemorrhage——Dr Andrew J Chittick, Burlington has been seriously ill with septicemia from a scratch wound

Personal—Dr Robert B Short, Union Mills, had a rib broken in a collision between two trains near Chicago August 9——Dr Edward A Willis formerly demonstrator of ophthalmic and aural surgery rhinology and laryngology in the department of medicine of the University of Michigan has located in Indianapolis

July Disease and Death—The July Bulletin of the State Board of Health says The health of the State in July was not so good as in July 1903 Diarrheal diseases led in prevalence, and typhoid fever which in last year was sixth in prevalence, stood fourth this month The typhoid fever epidemic in Indianapolis in June abated somewhat in July Tuberculosis showed an increase The total number of deaths was 2 772 an annual rate of 12 3 per 1,000 In the preceding month the rate was 10 1 per 1,000 and in July 1903 12 9 per 1 000 Pulmonary tuberculosis caused 346 deaths exceeding the same month of last year by 31 typhoid fever 68 diphtheria, 10 scarlet fever 5, measles 4, whooping cough 6 pneumonia 85, diarrheal diseases 296, cerebrospinal meningitis 20 puerperal fever 10, cancer 116, violence, 189, smallpox 5 The cities also show a higher death rate than the country in typhoid diphtheria, pneumonia, diarrheal diseases cerebrospinal meningitis puerperal fever cancer and violence

MARYLAND

The Medical and Chirurgical Faculty of Maryland will hold its semi annual fall meeting at Ocean City September 9 and 10

Resignation —Dr B Curtiss Miller for eight years resident physician in charge of the Western Maryland Hospital Cumberland, has resigned

Urges Sanatoria —City Commissioner Bosley of Baltimore in his annual report urges that the state and city jointly establish sanitoria for the treatment of consumption in the Blue Ridge Mountains

Kills Algae But Not Bacteria —Dr Stokes, city bacteriologist of Baltimore, reports that the copper sulphate used to purify the drinking water, while destroying algæ has no effect on bacteria

Cornerstone Laid.—The cornerstone of the addition to the Frederick City Hospital, to cost $10,000 and donated by Mrs Margaret M Hood of Frederick was laid, July 8 with impressive ceremonies

Gone to Investigate Typhoid Epidemic.—Dr Marshall L Price of the State Board of Health has gone to Mount Savage to investigate the typhoid fever epidemic there Up to August 10 there had been 93 cases and two deaths The outbreak is traced to a man who came to the town July 4 with the disease The deaths from the disease in Maryland average about 125 per annum

MICHIGAN

Appendectomies —Dr Levi J Lennox Detroit was operated on for appendicitis August 2——Dr Raymond A Clifford, Ypsilanti, who was operated on for appendicitis in Detroit July 17, is progressing favorably toward recovery

Sentenced for Abortion —Dr Scott Fraser Hodge Detroit convicted of manslaughter in connection with the death of Anna Lehmann was sentenced on August 2 to imprisonment for not less than six nor more than nine years in the state reformatory at Ionia

Personal.—Dr Oscar C Breitenbach has been appointed health officer of Escanaba——Dr Flemming Carrow has resigned the chair of ophthalmology and otology in the University of Michigan, Ann Arbor and will locate in Detroit Dr S Edwin Cruse, Iron Mountain, has been commissioned major and surgeon and assigned to the Third Infantry, M N G

Comparative Morbidity —For July compared with the average for July in the last ten years smallpox diphtheria and puerperal fever were more than usually prevalent and cholera morbus cholera infantum measles typhoid fever intermittent fever, remittent fever, dysentery, scarlet fever erysipelas, whooping cough and pneumonia were less than usually prevalent During July the diseases which are usually most prevalent during the summer months in the ten preceding years were less prevalent This lessened prevalence was probably due, in great part to the lower than average temperature during the month

The Most Dangerous Communicable Diseases —Meningitis was reported present in Michigan during July, 1904 at 8 places, whooping cough at 14 places, pneumonia at 20 places, diphtheria at 57 places, scarlet fever at 70 places, typhoid fever at 73 places, measles at 73 places, smallpox at 116 places, and consumption at 288 places Meningitis was reported at 1 place less, whooping cough at 6 places less, pneumonia at 54 places less, diphtheria at 4 places less, scarlet fever at 26 places less, typhoid fever at 2 places less, measles at 95 places less, smallpox at 62 places less and consumption at 6 places more in July 1904 than in June

MINNESOTA.

Personal.—Dr Andrew Henderson Merriam Park, St Paul, has gone to Scanlon Minn, to take charge of the sanitarium there——Dr Frank H H Allen has been elected health officer of Staples

Smallpox on the Wane —The number of new smallpox cases in the state for the week ended August 1 was only 6 the smallest number since the outbreak of the epidemic in the winter of 1898

St Paul's Health.—During July 284 births and 134 deaths were reported, the latter being equivalent to an annual death rate of 8 68 per 1,000 Only 22 cases of communicable disease were reported during the month

Graduates in Medicine —Hamline Medical School, at its twenty first commencement exercises conferred degrees on a class of 15——The College of Medicine and Surgery of the University of Minnesota Minneapolis, graduated a class of 82

State Society —The Minnesota State Medical Society, at its thirty sixth annual meeting held in St Paul, elected the following officers President Dr John W Bell, Minneapolis, vice presidents George S Wattam, Warren, Drs John Williams, Lake Crystal and James H Haines, Stillwater, secretary Dr Thomas McDavitt, St Paul, and treasurer, Dr Richard J Hill, Minneapolis

Tents for Isolation Hospitals —At a recent meeting of the Minnesota State Board of Health, it was decided to advise every township that does not have a special isolation hospital to buy at least one double tent for use as a portable hospital By the use of such tents, the spread of contagious diseases throughout entire families so common in the country districts, can be largely avoided The double tent is much more easily disinfected than a house and by erecting it in the yard the family of the quarantined person need not be inconvenienced

NEBRASKA

Personal —Dr Clinton I Sapp city physician of South Omaha has resigned and has been succeeded by Dr John Koutsky Dr William S White South Omaha, has been reappointed assistant physician of Douglas County

Many Graduate.—John A Creighton Medical College, Omaha, conferred diplomas on a class of 28——At the second annual commencement of the University of Nebraska Medical College, Omaha, a class of 30 received diplomas

New Officers —At the thirty sixth annual session of the Nebraska State Medical Society in Omaha, the following officers were elected President, Dr Robert C McDonald, Fremont, vice presidents, Drs John M Mayhew, Lincoln, and Charles L Mullins, Broken Bow, secretary, Dr A D Wilkinson, Lincoln, corresponding secretary, Dr H Winnett Orr Lincoln, and treasurer Dr James L Greene, Asylum

Electro Medical Institute Loses.—The State Electro Medical Institute" of Omaha, which sued a patient and was defeated on the ground that it was not authorized to practice medicine has had proceedings instituted against it by the State Board of Health, alleging that the Institute was a corporation, and that it assumed to practice medicine asking that it be enjoined and prohibited from practicing medicine or doing any business in the state The suit was decided in favor of the board and the injunction issued The Institute has appealed to the Supreme Court

NEW MEXICO

Hospital News.— The Sisters of the Sorrowful Mother are about to erect a hospital in Roswell——The Silver City Hospital Association has been merged into the Santa Fe Pacific Hospital Association

State Medical Society —The twenty third annual session of the New Mexico Medical Society held at Albuquerque, closed with the election of the following officers Dr Edwin B Shaw, Las Vegas, president, Dr J Frank McConnell, Las Cruces, Thomas B Hart, Raton and Percy G Cornish, Albuquerque vice presidents, Dr Guy H Fitzgerald, Albuquerque secretary and Dr Harry M Smith, Las Vegas, treasurer

Sanatoria.—A tent city sanatorium to cost $30,000, will be erected three miles north of Albuquerque and will be in charge of Dr James E Miller——Dr Robert E McBride has purchased a tract of land near Las Cruces on which he will conduct a sanatorium——The Las Vegas Hot Springs Sanatorium Company has been incorporated by Dr William T Brown, Lancaster, Wis, and others with a capital stock of $400,000 The company proposes to reopen the Montezuma Hotel as a sanatorium for wealthy consumptives and also to operate in connection a tent city where persons of limited means will be treated at actual cost

NEW YORK

Penitentiary Quarantined.—The Albany County Penitentiary has been quarantined because of smallpox

Diphtheria is Epidemic —Elmira is undergoing a mild epidemic of diphtheria In July 41 cases were reported, with one death

Buffalo Personals.—Dr Charles G Stockton is in Europe——Dr Charles von Bergen has taken an automobile trip through New England

Village in Quarantine —The entire village of Dresden has been placed in quarantine on account of an epidemic of small pox The Board of Health of Geneva has recommended general vaccination

Reception Hospital Incorporated—The reception hospital which is to receive and care for consumptives at Saranac Lake, was incorporated, August 10 by Drs Edward R Baldwin, Edward L Trudeau and others

Vienna Visitor—The Roswell Park Medical Club Buffalo listened to an address by Dr Bernard Panzer of Vienna on Diseases of the Accessory Sinuses of the Nose in Children' While in Buffalo Dr Panzer was the guest of Dr George F Cott

July Deaths in Buffalo—The monthly report of the Department of Health for July shows an annual death rate of 17 08 per 1,000 The principal causes of death were as follows Consumption, 44, cerebrospinal meningitis, 3, cholera infantum 63, diphtheria 7 typhoid fever 12, debility 32, cancer 20 apoplexy 23, meningitis, 12 valvular disease of the heart 24 pneumonia, 28 appendicitis, 7, diarrhea 11 gastritis 6 gastroenteritis 19 ileocolitis 10, diabetes 9, nephritis 15 and violence, 34 The total deaths for July were 541, as compared to 513 deaths for July, 1903

New York City

Sir Felix Semon, *D V O physician extraordinary to the King* of England, who is to deliver the address on laryngology at the St Louis Congress of Arts and Sciences will arrive in New York early next month where he will be entertained by Drs George M Lefferts and Emil Mayer

Death Rate Increases—*For the first quarter of the year there* were reported to the health department 12,590 deaths or 22 58 per 1,000 an increase of 1 60 points on the average for the last five years This increase was due to the prevalence of measles influenza accidents, and a very severe winter

Personal—Dr *William T Jenkins, formerly health officer of the Port of New York, has been appointed sanitary engineer* in the health department——Dr Patrick J Murray assistant sanitary superintendent for Brooklyn has been removed from office His successor has not been appointed

Cancer Hospital Appeals.—Mother Alphonsa Lathrop a *daughter of Nathaniel Hawthorne* has appealed for public assistance in maintaining the St Rose's Free Home and hospitals for the destitute cancer patients The work of caring for thirty or more of these patients is at a standstill

Contagious Diseases.—There have been reported to the sanitary *Bureau for the week ended August 6,* 366 *cases* of tuberculosis with 146 deaths 232 cases of diphtheria with 33 deaths, 133 cases of measles with 6 deaths, 68 cases of scarlet fever, with 2 deaths, 67 cases of typhoid fever with 13 deaths, 3 cases of smallpox *and* 11 *cases of varicella*

Typhoid Fever Epidemic—The Board of Health has made a house to house canvass of the neighborhood of the Jerome Park reservoir, where a colony of Italians are at work, and this has resulted in finding twenty five cases This reservoir is not being used now and therefore the city of New York is not *endangered* Numerous springs are to be found which bubble up from the floor of the big basin and the board is inclined to believe that here may be found the source Each of these suspected holes has been labeled 'poison" in English and Italian The water has not yet been examined for the germs of the disease

PENNSYLVANIA

Much Typhoid in Pittsburg—On August 9 33 new cases of typhoid fever were reported to the Pittsburg Bureau of Health

Typhoid at West Chester—Thirty cases of typhoid fever have been reported to the board of health within a short time Efforts are being instituted by the board to discover the cause of the outbreak, as the town has always been remarkably free from the disease The present rate is only 3 to each 1 000 population but this is extremely high *as compared* with the record of former years

Philadelphia

New Superintendent for Blockley—Mayor Weaver has appointed William F Defrates superintendent of the Philadelphia Hospital, to succeed the late Robert M Smith

New Medical Inspectors—Dr J Frank Wallis was recently appointed district medical examiner in place of Dr Andrew J Maher, resigned——Drs Howard G Fretz and Harlan Shoemaker have been appointed assistant medical inspectors in the bureau of health, vice Drs Harold B Ward and William P Hearn

Bequests—By the will of the late *Benjamin F Teller,* who died July 15, the Jewish Hospital Association receives $35,000, for the establishment of free beds——The will of the *late Cornelia Thompson* devises $10,000 to the Presbyterian Hospital for *the endowment of two free beds* and $5,000 for a free bed in the Children's Hospital

Health Report—The increase in typhoid fever during the past three weeks was particularly noticeable in the reports for *the last seven days* One hundred new cases and 11 deaths were *recorded for the week ending July 13* as compared with 84 cases and 5 deaths for the preceding seven days There were in all 191 cases of contagious disease reported, as follows Diphtheria, 40, scarlet fever, 51, typhoid fever, 100 The city still *remains totally* free from smallpox, no cases being reported since July 9 The *general death rate* is *higher,* the total deaths numbering 141 This is an increase of 13 over those of last week and 15 more than for the corresponding *period of last year* Seventy five of the deaths occurred in infants under two years of age

SOUTH CAROLINA

Personal—Dr Fred L Potts, Spartanburg, has returned from Philadelphia after having undergone an operation for appendicitis——*Drs H W Shaw and Walter D Wright* have been made members of the board of health of Langley

To Transfer Hospital to Society—The Medical Society of South Carolina trustees under the will of Thomas Roper, proposes that the present Charleston City Hospital be conveyed to *it for a nominal sum, and that the entire management* of the institution be entrusted to the society The society agrees to expend about $100,000 in the improvement of the hospital buildings, which practically involves their reconstruction and *adaptation to conform to modern scientific ideas*

VIRGINIA.

Smallpox—It is reported that there are more than a hundred cases of smallpox in Buchanan County 25 or 30 of which are in Grundy the county seat The circuit judge, on this account, has decided not to hold the regular session of court

Mortality of 1903 in Richmond—During 1903, 884 white persons and 1,051 colored died in Richmond, a rate of 19 35 per 1,000 for the former, and 27 84 per 1,000 for the latter In May occurred the greatest mortality, 201 *and in August the* least, 123

College Incorporated—The University College of Medicine Richmond, has been granted a charter by the corporation commission The incorporators were Drs J Allison Hodges, Stuart McGuire, Paulus A Irving and Landon B Edwards, all of Richmond

Personal.—Dr Elisha Barksdale of Halifax County has succeeded Dr A D Louthan as resident physician at Memorial Hospital, Richmond——Dr O C Brunk has succeeded Dr Hugh C Henry *as first assistant physician at the Central State* Hospital, Petersburg——Dr Herbert M Nash, Norfolk, has succeeded Dr Frank A Walke, deceased, as surgeon of the Pickett Buchanan Camp of Confederate Veterans

GENERAL

Osler to Go to Oxford University—Dr William Osler has accepted the regius professorship of medicine at Oxford University in *succession to Sir John Burton Sanderson* He will assume the duties of the new position next spring after completing the school year of 1904 5 at Johns Hopkins The appointment has been approved *by King Edward Dr Osler* reached New York, August 14, *on the* White Star liner *Cedric and is now* with his family at Murray Bay, below Quebec, Canada Dr Osler has been considering this position for some time and has felt the need of a change from the extraordinary pressure of work *now on him His new* position will give him *opportunity* for more literary work in connection with the mass of clinical data that he has accumulated in his work in this country

FOREIGN

Medical Study Trips.—The German medical study trip to the spas of Germany September 7 17, will be diversified by addresses by Brieger, chief of the Berlin Hydrotherapeutic Institute Flügge of sputum droplet fame Goldscheider, Ott, chief of the unique maternity at St Petersburg Rosin, *Stern and* von Strümpel *Dr W H Gilbert of* Baden Baden has the *matter in* charge, as mentioned on page 1619 of the last volume The French study trip is in charge of Landouzy and will start from Lamotte September 3 and disband September 15 after visiting Vichy and other spas in Auvergne These study trips are becoming more and more popular every year, and at fact hundreds of physicians for an inexpensive outing with congenial enthusiasts

Bacteriologic Institutes in the French Colonies.—France has organized institutes in her colonies modeled after the Paris Pasteur Institute Madagascar, Algiers Tunis, New Caledonia, Senegal each has one or more, and French Indo China has three It was in one of these Cochin China laboratories that the idea occurred to Calmette to utilize the buffalo for vaccine production, and here also he discovered the ferments utilized now in the production of alcohol Here also he commenced his studies on snake poison which resulted in the discovery of his antivenom serum Yersin's work in one of these laboratories resulted in the production of his anti plague serum A Colonial Congress" has recently been held at Paris which outlined new tasks for the future but also showed that more had already been accomplished in the way of hygiene and education than had been realized

Pulmonal Infusion.—Jacob's published communication was reviewed in The Journal of July 30 page 361, and also on page 434, August 6 In the concluding portion he relates his clinical experience with 5 patients treated by direct infusion of tuberculin into a lower bronchus The communication was first presented at a meeting of the Berlin Medical Society and Westenhoeffer created a sensation by stating his impression that the infusion had hastened the fatal termination in one of the patients He cited the "office register of the hospital—the Charite—in confirmation of these statements but Jacob declared that this register was not kept strictly accurate, the main reliance being on the official clinical record kept in each ward This contention between the physicians led to a spirited debate and Jacob sent a letter to a Berlin daily on the subject As the 'office register" is accepted as testimony in the courts, this official announcement as to its unreliability attracted public attention Jacob stated that the patient in question was almost moribund, and that the tracheotomy and infusion were done as a possible last resource The denunciations of his conduct were so bitter Lazarus and Kohn sustaining Westenhoeffer's assertions, that the appointment of a committee to investigate the matter was considered but no official steps were taken He was accused of suppressing certain circumstances and cases in his report and of performing tracheotomy on subjects presenting no indications for such a measure His contract with the hospital expires in October and no steps have been taken by the authorities to renew it

Queries and Minor Notes.

Anonymous Communications will not be noticed Queries for this column must be accompanied by the writer's name and address but the request of the writer not to publish his name will be faithfully observed

CHARGES BETWEEN NURSES AND PHYSICIANS

R. K City of Mexico writes Is it ethical for a physician to charge a nurse for medical attention? There is a case here in this city which is causing much comment A nurse was called on a smallpox case and the physician advised her to be vaccinated and he charged her $1 50 It did not take and he vaccinated her the second time charging her the same price The girl has since had typhoid fever and now is paying him with what little money she can earn for his services through the fever He is a graduate of the University of Michigan

Answer.—In reply to the opening question of our correspondent it may be freely stated that there is no general obligation resting on medical men to give gratuitous professional attention to nurses We are not aware that nurses have ever served physicians or members of their families—except because of personal reasons—for less than they would have asked laymen for like service Therefore of course they can expect no concession in return In spite of this fact however physicians usually are generous and render to a nurse for professional service a bill much less than would be asked of a layman In case the nurse is an unusually capable one with whom the physician has been closely associated in the care of the sick she commonly is not called on for a fee That however is a matter of personal relation not of established interchange of courtesy As has before been observed the relation between physician and nurse has never been clearly defined It is to be regretted that this was omitted from our new and admirable Principles of Ethics for there are many points of contact between the two callings that need elucidation For instance regarding the point at issue the claim is set up for the nurse that attendance on a physician in illness takes all her working time cutting off entirely her means of support and that therefore gratuitous service is too much to ask This contention seems irrefutable so that all the nurse could offer would be some concession in the weekly wage but so far as we are informed this is not the custom As before noted the physician should be entirely governed by the local circumstances *If he attends a nurse in a long serious illness* he should be entitled to some compensation If the service is small such as a vaccination and the nurse is well known to the physician, it certainly is customary to make no charge Regarding vaccination we believe it to be usual in this country for the physician in any case to make no charge for a revaccination when a recent vaccination has failed to take From the above observations our correspondent will gather that such a course toward a nurse as that described by him appears wholly indefensible but that before final judgment could be pronounced on the ethics of such a particular case it would be necessary to learn the circumstances influencing the physician to adopt this course toward this nurse

EFFECT OF MORPHIN IN PREGNANCY

S K of Dakota asks 1 Does the excessive administration of any drug produce permanent insanity? If so what drugs? 2 Is it advisable to administer daily large doses of morphia to a pregnant woman *for three months prior to her confinement for supposed gastric ulcer? 3 What effect will it have on the child?* 4 Is it right to treat a general pruritus occurring in later months of pregnancy with daily hypodermatic injections of morphia? 5 Does continuous administration of morphia produce a general erythematous eruption with general pruritus?

Answer – 1 Temporary 2 Morphin is given most frequently *during pregnancy to prevent labor in cases of threatened labor or* abortion It may be employed to meet other indications but it should not be used for ulcer of the stomach The approved method of treating this pathologic condition during pregnancy as in the non pregnant state is to keep a patient in bed and put nothing into the stomach for ten to fourteen days relying wholly on rectal feeding Then little by little careful feeding is begun. 3 Morphin as well as other alkaloids and soluble drugs will pass through the placenta into the blood of the child The fetus is affected by morphin administered to the mother but to what extent is a matter of dispute No doubt a dose dangerous to the mother may be dangerous to the fetus *Probably* a moderate therapeutic dose will not injure the child When the mother takes morphin regularly *during pregnancy the fetus can acquire the morphin habit and* suffer afterwards from its sudden withdrawal 4 and 5 Genital and vulvar pruritis occurring during pregnancy are symptoms of gravidal intoxication and should be controlled by eliminants diet and soothing washes or salves Morphin is not necessary nor desirable since it interferes with elimination and so tends at times to increase the trouble

TIME TO TAKE ALKALIES TO MAKE URINE ACID

Dr William C Riley San Francisco writes Regarding inquiry of J W B Virginia, page 275 July 23, 1904 as to proper time to give alkalies to make the urine acid also concerning answer by J T Howard page 342, July 30 1904 it is pertinent to enquire does administration of alkalies *ever* make the urine acid? Clinical and experimental data show the contrary without splitting hairs I might ask what is an alkali and what is an alkaline reaction? Sodium bicarbonate ($NaHCo_3$) is usually regarded as an alkali Is it? Chemically it is an acid salt. Physiologically it acts like an alkali It acts as an alkali with litmus and with all other indicators used to determine such facts except phenolphthalein with the latter the pure salt (free from carbonate) acts as an acid simply because carbonic acid is sufficiently strong (to use a common but misleading term) to decompose the weak saline combination of the indicator Regarding sodium phosphates there are three well defined salts—the first two 1 NaH_2Po_4 and 2 Na_2HPo_4 (ordinary phosphate of soda) being chemically acid salts the third 3 Na_3Po_4 is chemically a neutral salt To the taste and to litmus numbers two and three are alkalies To state that a given chemical is acid or alkaline one must state the indicator used Thus a solution of sodium phosphate neutral to litmus is alkaline to diamidoazobenzole alizarin (alizarin monosulphonate of sodium) methyl orange and tropeolin and also to the tongue It is acid to phenolphthalein (unless boiled) A solution of sodium phosphate which is acid to litmus and also to taste is alkaline to all the other indicators save phenolphthalein A solution of sodium phosphate alkaline to litmus and to taste is alkaline to all other indicators save phenolphthalein and it reacts red to that when boiled. ($NaHCo_3$ being split up into Na_2Co_3 and Co_2 the latter being driven off) So all theory aside how in the world can one obtain an acid salt of phosphoric acid by adding alkalies to a neutral salt, or even to an acid salt of the same base It is too utterly absurd.

RELATION OF SEX OF CHILD TO THE RELATIVE AGE OF PARENTS

W K L of Havana writes Is there any law in regard to the influence of age of married couples on their *offspring?* I understand that if the mother is older than the father the children begotten from such *parents will be females*

ANSWER—According to the theory of Hoffacker and Sadler which was promulgated about seventy five years ago the sex of the child is likely to be the same as that of the elder parent when there is disparity in the ages of the parents This theory has been overthrown by Berner and others Certain statistics tend to prove the contrary namely that the sex of the child is more apt to be that of the younger parent The problem of the determination of sex is still unsolved and there are no collections of statistics or other data from which we can deduce rules available for practical application

INFANT SWALLOWS AND SAFELY EXPELS LARGE WIRE STAPLE

DR C D SCRATTON Rothville Mo writes About July 18 1904 I was consulted by a mother in regard to her 9 months old baby swallowing a common fence staple She said she felt it as it passed into the gullet sharp points down The child was limp and pale for a few minutes when all was as well as usual I told her that she was probably mistaken as it was almost impossible for a child to swallow such a thing The anxious mother continued to watch however and at the end of 17 days the staple passed without in any way harming the child It measured 1¼x½ inch and was as sharp as these instruments usually are

ANSWER—Although such sharp objects often pass through the canal without doing harm they sometimes lodge or inflict other injury If a child is old enough free administration of slippery elm bark may be tried Cases are reported in which the fibers have enveloped the sharp object completely protecting the mucosa

Marriages.

CLARA L KEMBAL M D Bloomfield Iowa to C H Cronk of Tama Iowa, July 31

GEORGE A HARTMAN M D to Miss Agnes Graham both of Baltimore August 1

W FRANK ASHMORE M D to Miss Luna Cater both of Anderson, S C, August 2

DAVID L AXILROD M D to Miss Lillian Aronsohn both of St Paul, Minn August 3

O E SPILLER M D Mauldin Mo to Miss Ruby Larkey of Memphis Tenn, August 9

ALCIMUS H BASKIN, M D, to Miss Agnes Hermena Muller both of Atlanta, Ga August 3

RODERICK B CHISHOLM, M D, to Miss Belle Hayes both of La Porte City Iowa August 3

JUSTIN J LEAVITT, M D, Molalla Ore to Miss Sophia M Boyles of Portland Ore, August 2

CHARLES H LUDLOW M D Covington, Ind, to Miss Coralie Daniels of Savoy Ill, in November 1903

HARRY A STALKER, M D Pond Creek Okla, to Miss Maude Webster of Durand Ill at Rockford Ill August 4

CHARLES EDWIN FRENCH M D San Francisco, Cal, to Miss Gertrude Twineham of Cincinnati Ohio at Princeton Ohio, August 16

Deaths.

Orlando Brown, M D Yale University Medical Department New Haven, Conn 1851 assistant surgeon of the Eighteenth Massachusetts Volunteer Infantry later inspector of hospitals, and in 1865 made colonel of the Twenty fourth U S Infantry, brevetted brigadier general for gallant conduct in the service, organizer of the Bureau of Freedmen and Refugees, who resigned his commission in 1869, and resumed practice in Washington, Conn, once president of the Litchfield County Medical Society and president of the Connecticut State Medical Society in 1889, died at his home in Washington August 4 after an illness of several months, aged 77

John O'Flaherty, M D Albany (N Y) Medical College, 1864, a member of the Connecticut State and Hartford County medical societies, president of the Hartford Medical Society, assistant surgeon of the One Hundred and Seventeenth New York Infantry in the Civil War for several years president of the medical board of St Francis Hospital died at his home in Hartford, July 31 from nephritis after an illness of seven months aged 62

Albert Preston Fulkerson, M D Jefferson Medical College Philadelphia, surgeon in the Confederate service during the Civil War died at the home of his brother in Lexington Mo, from meningitis after an illness of three weeks, aged 68

Romeo F Chabert, M D New York University, New York City, 1856 of Hoboken N J, founder and consulting surgeon of St Mary's Hospital and consulting physician to Bayonne Hospital, died at his summer home in Asbury Park, N J, August 1, after an operation for intestinal obstruction, aged 76

Walter J Byrne, M D Medical Department St Louis University, 1848, surgeon of the Ninth Kentucky Infantry, C S A, during the Civil War, some time superintendent of Central Kentucky Hospital for the Insane, Lakeland died at his home in Russellville, Ky, August 1, after a short illness, aged 80

George W Menees, M D University of Nashville (Tenn) Medical Department, 1855, a member of the American Medical Association, and one of the oldest and best known physicians of Robertson County, Tenn, died at his home in Springfield from peritonitis, August 1, after an illness of two days, aged 70

Frank J Havlicek, M D Medical Department of Adelbert College of the Western Reserve University, Cleveland, Ohio 1882, a member of the American Medical Association, and a well known practitioner of Cleveland, died suddenly at his home in that city, August 7, from cerebral hemorrhage, aged 45

A Carter Webber, M D Harvard University Medical School, Boston 1849, the dean of the medical profession of Cambridge, Mass, who retired from practice in 1900, died suddenly at the home of his son in Manchester by the Sea Mass, August 5, from acute bronchitis, aged 78

Henry M W Moore, M D Columbus (Ohio) Medical College, 1885, a member of the American Medical Association and a veteran of the Spanish American War died at his home in Columbus, August 6, from an overdose of chloral aged 42

Felix F Cassaday, M D Jefferson Medical College, Philadelphia 1867, a member of the American Medical Association and of the Philadelphia County Medical Society, died at his home in Philadelphia, from apoplexy, August 2, aged 62

Charles Thomas Varnon, M D University of the State of Missouri Medical School, Columbia, 1876, coroner of Audrain County, Mo died at his home in Mexico, Mo from Bright's disease, July 24 after a long illness aged 53

John N Woodruff, M D College of Physicians and Surgeons in the City of New York state senator in 1897 probate judge for several years died suddenly from heart disease at his home in Sherman, Conn July 18, aged 68

John Leonard Evans, M D University of Louisville (Ky) Medical Department, 1888, of Colorado Springs Colo died at Norton Infirmary, Louisville July 30, from pulmonary abscess, after an illness of four years, aged 38

Charles Newton Thompson, M D Bellevue Hospital Medical College, New York City 1884 of New York City for many years surgeon of the Ninth Infantry N G, N Y, died at Nantucket Mass August 7, aged 54

Francis B Ambler, M D Denver College of Medicine University of Denver, Colo 1897, of Northville Mich died at St Mary's Hospital, Detroit, August 7, one day after an operation for intestinal obstruction, aged 38

James Henry Reynolds, M D Detroit (Mich) Medical College, 1871, formerly mayor of Adrian, Mich, died at his home in that city from cerebral hemorrhage July 30, after an illness of one week aged 59

Abial W K Newton, M D Department of Medicine of the University of Pennsylvania, Philadelphia, 1871, some time coroner of Suffolk County, Mass died at his home in Boston August 1, aged 68

David Y Winston, M D Department of Medicine of the University of Pennsylvania Philadelphia, 1888 died at his home in Clarksville, Tenn August 7, from typhoid fever, after a short illness, aged 42

Thomas Franklin Thornton, M D Detroit (Mich) Medical College, 1873, of Grand Ledge, Mich, died at St Mary's Hospital, Detroit, August 3 from diabetic gangrene, after an illness of three weeks

Evans Prothro, M D Memphis Hospital Medical College, 1898, of England, Ark, died at the home of his brother near Little Rock, Ark, from sunstroke, after an illness of only a few hours, aged 32

Henry S Kimmel, M D Cincinnati College of Medicine and Surgery 1861, a member of the state and county medical societies, died at his home in Dayton, Ohio, August 6, aged 70

Gabriel H Hill, M D Louisville (Ky) Medical College, 1874, of Charlottesville Va, died at Spartansburg, S C, July 15, from the effects of a fall received several weeks before, aged 69

Richard C Bond, M D, Miami Medical College, Cincinnati, 1857 of Aurora Ind died at the home of his sister in Quiet Dell W Va, July 7 from pneumonia after an illness of five days aged 83

Robert Milbank M D New York University New York City 1878 of New York City visiting physician to New York Infant Asylum, died at Byram Shore N Y from apoplexy August 4 aged 66

Alfred A Wall, M D Department of Medicine of the University of Pennsylvania Philadelphia 1849 of Tuscumbia Ala died at the home of his son in Jasper Ala July 11 aged about 80

R Bliss Kennedy, M D Beaumont Hospital Medical College St Louis 1901, died at his home in Burlington Junction Mo July 26 from the effects of a self inflicted gunshot wound of the head

Joseph Weaver, M D Medical College of Ohio Cincinnati 1838 who retired from practice in 1870 died at his home in Miamisburg Ohio July 19 after an illness of eight days aged 87

John McClary Steele, M D Laval University Medical Department Quebec 1890 while suffering from melancholia shot and killed himself at his home in Worcester Mass August 1 aged 37

James Hutchinson, M D Missouri Medical College St Louis 1876 died at his home in Boling Kan from disease of the digestive apparatus August 3 after an illness of four months aged 62

William B Rehling, M D Rush Medical College Chicago 1903 of Alhambra Ill, died at the home of his mother in Waterloo Ill from typhoid fever July 28 after an illness of three weeks aged 26

William C Darnall, M.D Vanderbilt University Medical Department Nashville Tenn 1890 died at his home in Huntsville Ala from consumption July 28 after a lingering illness aged 35

Benjamin F Egleston, M D University of Buffalo (N Y) Medical Department 1882 died from apoplexy at his home in Churchville N Y July 25 after an illness of only a few hours aged 58

Robert L Gattis, M D University of Maryland School of Medicine Baltimore 1888, died at his home in Chapel Hill N C July 29 from typhoid fever after an illness of six weeks aged 34

George A Thomas M D Louisville Medical College 1878 a member of the American Medical Association surgeon to the Indiana Railroad died at his home in Linton Ind August 1

Thomas Ballard McDow, M D Medical College of the State of South Carolina, Charleston, 1879 was found dead in bed at his home in Charleston July 26 from heart disease aged 49

John J Adderhold, M D Atlanta (Ga) Medical College 1891 of Worth, Ga, died at the Macon City Hospital July 30 from pneumonia a short time after a mastoid operation aged 38

Clarence M Boyd, M D Northwestern Medical College of St Joseph Mo, 1892, of St Joseph died at Ensworth Hospital in that city, July 17, from cerebral hemorrhage aged 33

George Ernest Mayhew, M.D College of Physicians and Surgeons of Chicago, 1897, of Red Bluff, Cal, died at Colvear Springs, Cal, July 19, after a long illness aged 32

Henry Venne, M.D Faculty of Medicine of Queen's University, Kingston, Ont 1861 died at the Old Folks' Home Mattoon Ill from Bright's disease, July 14, aged 70

Martin B Kellar, M D Miami Medical College Cincinnati, 1868, died at his home in Vallejo, Cal, July 8, from heart disease after an illness of several months, aged 61

C A Stanfield, M D Memphis (Tenn) Medical College died at his home in Toledo Ark, August 3, after a lingering illness

William R McLaren, M D Illinois, 1871 died suddenly at his home in Detroit, Mich, July 28, from angina pectoris, aged 55

Charles A Scribner, M D Illinois 1891 died suddenly at his home in Dalton, Mich June 28, from angina pectoris aged 44

John S. Lampman, M D Pennsylvania 1859, died at his home in Wilkesbarre, Pa August 5, after a short illness aged 65

J T Stoddard, M D, of Jonesboro, Ark, died at Orlando Fla July 23 from Bright's disease, after an illness of two years

Helen Gray Da Costa, M.D Woman's Medical College of Chicago 1898, died March 13, at Princeton Ind aged 29

David B Taylor, M D Ohio 1869, died suddenly at his home in Millburn Ill, August 1, from heart disease, aged 78

Thomas W McGaughey, M D Chicago Medical College, 1892, died at his home in Pennington Point, Ill, February 28

Guy W O Mitchner, M D Barnes Medical College, St Louis, committed suicide at Guthrie, Okla, March 28, aged 25

C C McKinley, M D College of Medicine and Surgery, Cincinnati, 1865, died recently at Champaign, Ill, aged 76

Mark R Wright, M D Medical College of Alabama, Mobile 1873, died at his home in Knox, Ind, June 25 aged 68

Lewis B Stewart, M D Indiana, 1897, died at his home in Marengo Ind, August 1, from heart disease aged 83

Death Abroad

William Alexander McKeown, M D, R U S 1869, Fellow of the Royal Academy of Medicine of Ireland, surgeon to the Ulster Eye, Ear and Throat Hospital Belfast, lecturer in ophthalmology and Otology, Queen's College, Belfast, some time president of the Ulster Medical Society, and of the North of Ireland Branch, British Medical Association an ophthalmologist of more than local renown, whose most important advances in his specialty were the use of the magnet for the removal of metallic foreign bodies from the eyeball, and the operative treatment of immature cataract died at his home in Belfast, July 9, aged 60

Sir Frederic Bateman, M D Aberdeen, 1850, M R C S Eng, 1849, M R C P Lond, 1866, F R C P Lond, 1876, L S A, 1850, eminent as a physician, scientist and psychologist, a member of many English and foreign learned societies, laureate of the Academy of Medicine of France, and medical and sociological author of repute, consulting physician to Norfolk and Norwich Hospital, knighted by the Queen in 1892, died at his home in Norwich England, August 10, aged 80

The Public Service.

Army Changes

Memorandum of changes of station and duties of medical officers U S Army week ending Aug 13 1904

Weed Frank W asst surgeon ordered to proceed from Fort McHenry to Fort Howard Md for temporary duty

Freeman Paul L asst surgeon ordered to proceed from Fort Slocum N Y to Fort Warren Mass for temporary duty

Reilly John J asst surgeon leaves Jackson Barracks La on thirty days sick leave

Hathaway L M asst surgeon relieved from duty at Fort Davis Alaska and ordered to Fort Gibbon, Alaska

Heizmann Chas L asst surgeon general granted fifteen days leave of absence

Dale F A asst surgeon granted thirty days leave of absence about September 1

Ashburn P M asst surgeon left Fort Missoula Mont with troops on practice march

Gosman Geo H R asst surgeon assignment to duty with troops at maneuvers Manassas, Va is revoked

Little Wm L asst surgeon ordered to accompany troops from Camp Geo H Thomas Ga and for duty with same at maneuvers Manassas Va Aug 26 1904

Reno Wm W asst surgeon assignment to duty at Manassas Va during maneuvers revoked

Reno Wm W asst. surgeon relieved from duty at Fort Crook Neb and ordered to duty with troops at the Louisiana Purchase Exposition St Louis

Church James R, asst surgeon sick leave of absence extended two months

Fyster Theo C asst surgeon reported at Ancon Canal Zone, Isthmus of Panama left West Point N Y July 7 1904

Burney Chas N asst surgeon ordered to accompany detachment hospital corps from Fort Jay N Y to Gainesville Va not later than Aug 18 1904

The following named medical officers will report Aug 18 1904 to the Division surgeon First Provisional Division near Manassas Va Capt W F Truby at Fort Preble Me. Capt. H S Greenleaf Fort Moultrie S C First Lieut Geo H Crabtree Fort Jay N Y First Lieut Wilfrid Turnbull Fort Strong Mass First Lieut Geo W Jean Fort Wadsworth N Y First Lieut Jas I Bevans, Fort Barrancas Fla

To the Division surgeon Second Provisional Division near Thoroughfare Va. Capt P C Fauntleroy Madison Barracks N Y Capt B H Dutcher Fort Hancock N J Capt F H Hartnett, Key West Barracks Fla Capt Clyde S Ford Fort H G Wright N Y First Lieut Wm L Little Camp Geo H Thomas Ga.

To the First Provisional Division near Manassas Va Major Charles Willcox Fort Totten N Y to accompany troops from Fort Slocum N Y Major Jos T Clarke Fort Ethan Allen Vt to accompany troops from that post Major Henry A Shaw Fort Adams R I Capt Jas S Wilson to accompany troops from Fort Myer Va Capt F R. Schreiner Fort McHenry Md First Lieut Chandler P Robbins, Fort Terry, N Y First Lieut Henry S Kiersted Fort Myer Va to accompany troops from Washington Barracks D C First Lieut Frank T Woodbury Plattsburg Barracks N Y to accompany troops from that post First Lieut Compton Wilson Fort Howard. Md First Lieut I W Patton Fort Hamilton N Y to accompany troops from that post to

Gainesville, then to proceed to Maneuver Camp No 1 First Lieut William Roberts Fort Caswell, N C First Lieut Robert M Thornburgh Fort Warren Mass, First Lieut C C Whitcomb, Fort McKinley, Me, First Lieut Park Howell Fort McPherson, Ga to accompany troops from that post First Lieut Percy L Jones, Fort Monroe Va, First Lieut Howard H Bailly Plattsburg Barracks, N Y, to accompany troops from that post

To the Second Provisional Division near Thoroughfare Va Major Henry C Fisher, Camp Geo H Thomas Ga, to accompany troops from that camp Capt H M Hallock Fort Porter N Y to accompany troops from that post Capt Ira A Shimer, Fort Niagara N Y to accompany troops from Madison Barracks, N Y to which place he will proceed in due time Capt Douglas F Duval Fort Williams Me First Lieut Walter Cox Fort Banks Mass First Lieut A W Williams, Fort Greble R I, to accompany troops from Fort Jay N Y First Lieut Wm H Brooks Fort Washington, First Lieut Reuben B Miller, Fort Screven Ga

Stallman George I contract dental surgeon Kuhn Charles F and Reddy Joseph W contract surgeons sailed August 1 from San Francisco on the transport *Logan* for Manila P I The first named has just entered the service the other two are returning from leaves of absence spent in the United States

Vaughan Milton contract surgeon relieved from further duty in the Philippine Division and directed to proceed at the expiration of his present leave of absence from Little Rock Ark to Fort Douglas Utah for duty

Foulkes Pruce contract surgeon returned July 28 to his proper station Vancouver Barracks Wash from temporary duty at American Lake Wash

Navy Changes.

Changes in the medical corps, U S Navy for the two weeks ending Aug 13 1904

Grunwell A G surgeon ordered to the *Dixie*

McDonnold P E P A surgeon commissioned P A surgeon with rank of lieutenant from July 2, 1904

McDonnell W N A A surgeon detached from the *Marcellus* and ordered to the Naval Recruiting Rendezvous Baltimore Md

Dabney V A A surgeon detached from the Naval Recruiting Party No 3 and ordered home to wait orders

Dean R C medical director detached from duty as a member of the Naval Retiring Board Washington D C and ordered home

Duncan G F A A surgeon detached from the Naval Recruiting Party No 2 and ordered to the *Franklin*

Janney W H A A surgeon detached from Naval Recruiting Party No 1 and ordered to the *Marcellus*

Lung G A surgeon detached from the *Hancock* and ordered to the *Kentucky*

Guest M S P A surgeon detached from the *Kentucky* and ordered to Washington, D C Sept 1 for examination for promotion and then to wait orders

Asserson F A, asst surgeon detached from the *Kentucky* and ordered home to wait orders

Dessez P T asst surgeon detached from the Naval Academy and ordered to the *Kentucky*

Marine-Hospital Service

Official list of the changes of station and duties of commissioned and non commissioned officers of the Public Health and Marine Hospital Service for the seven days ended Aug 4 1904

Purviance Geo asst surgeon general granted extension of leave of absence from June 20 to June 30 inclusive

Banks C E surgeon granted leave of absence for one month and fifteen days from August 12

Sprague E K P A surgeon to report to Surgeon G W Stoner Immigration Depot New York, for duty

Greene J B P A surgeon on the return of Asst surgeon H McG Robertson relieved from duty at New York (Stapleton) and directed to proceed to Fort Stanton as inspector of unserviceable property On completion of this duty to remain at Fort Stanton and await further orders

Lavinder, C H P A. surgeon relieved from duty at Delaware Breakwater Quarantine and directed to proceed to New York (Stapleton) and report to medical officer in command for duty and assignment to quarters

Foster M H P A surgeon granted leave of absence for fourteen days

Trotter F E asst surgeon granted leave of absence for ten days from August 5

Fahrenburg L P H asst surgeon to assume command of service at Delaware Breakwater Quarantine, relieving P A Surgeon C H Lavinder

Salmon T W asst surgeon granted leave of absence for seven days from Aug 2 1904, under Paragraph 191 of the Regulations

Porter J Y sanitary inspector to proceed to Havana Cuba for special temporary duty and to inspect the disinfecting steamer *Senator*

Brice J W A A surgeon granted leave of absence for thirty days from September 20

Foster, J P C A A surgeon granted leave of absence for thirty days from August 1

Stuart A F A A surgeon Department letter of June 22 granting leave of absence for thirty days from July 1 amended to read twenty one days

Rogers, Edward pharmacist granted leave of absence for sixteen days from August 5

Troxler R F pharmacist, granted leave of absence for thirty days from September 5

Neves Geo pharmacist granted leave of absence for thirty days from August 27

BOARD CONVENED

Board to meet at Port Townsend Wash for the physical examination of candidates for second assistant engineer in the Revenue Cutter Service Detail for the board P A Surgeon J H Oakley chairman A A Surgeon W F Patrie recorder

PROMOTIONS

Asst Surgeons T B McClintic, Joseph Goldberger and W A Korn commissioned (recess) as P A surgeons to rank as such from July 28 July 27 and July 27 1904 respectively

Health Reports

The following cases of smallpox yellow fever cholera and plague have been reported to the Surgeon General Public Health and Marine Hospital Service during the week ended Aug 12, 1904

BRITISH MEDICAL ASSOCIATION

Seventy Second Annual Meeting, held at Oxford, July 26 30, 1904

(Continued from Page 510)

The President's Address

The subject of the address of the president, Dr William Collier, was "The Growth and Development of the Oxford Medical School" He contrasted the present condition with that in 1878, when a correspondent of the *British Medical Journal* wrote a long letter complaining that the study of medicine was completely overlooked at Oxford, that no teaching was being given in the preliminary medical subjects, and that the medical faculty had practically ceased to exist. Dr Collier stated that as a result of the controversy following this letter the subject was taken up by the British Medical Association and the present medical school was established

Dr Collier spoke of the influence of the university student on other medical students, referring to the time when any outbreak of rowdyism in London was attributed to medical students, and ascribing the change for the better to the influence of university graduates who are generally older men with a more settled purpose in life and a clearer and better idea of what constitutes good and bad form He pointed out that the standard of general culture is distinctly raised by a university education and correspondingly the status of the medical profession

Dr Collier referred to famous men who had been associated with Oxford in the past notably Linacre founder of the Linacre professorship of comparative anatomy, Harvey the discoverer of the circulation of the blood Willis famous for his description of the anatomy of the brain particularly the circle of Willis Wren the architect of St Paul's Cathedral who made the drawings to illustrate Dr Willis' work on the anatomy of the brain Radcliffe who left the bulk of his estate to the college to build a library which is now known as the Radcliffe Library Sydenham and many others

In conclusion Dr Collier spoke of the previous meetings of the association in Oxford the first of which was in 1835 and was attended by 300 members The second meeting at Oxford was in 1852 and the third in 1868 He spoke of the influence of the association not only in Great Britain but throughout the empire the association having branches in India and the colonies He reminded the association that its power for good was due to the united and unremitting labors of many workers and that no hasty nor unwise action must be allowed to jeopardize its further development

Report of Hospital Committee

The following report of the hospital committee was adopted 1 Poverty and sickness shall be the conditions for admission of all patients for hospital treatment 2 No charge for treatment shall be made though voluntary contributions may be accepted 3 The production of subscribers letters shall cease to be compulsory and that where possible the system shall be abolished 4 Some means of investigation into the circumstances of applicants for relief shall be employed in all medical charities, and where possible a special officer shall be appointed for this work 5 Except in emergencies before a patient is admitted into any hospital evidence shall be obtained on two points, (a) that the patient is not in a position to pay for treatment, (b) that the case is, from the hospital point of view, suitable for treatment 6 All cases of serious accident and severe sudden illness shall be attended on their first application, and if deemed eligible for further treatment shall be referred to the appropriate department of the hospital but if ineligible shall be referred for treatment elsewhere 7 All cases of trivial accident or illness deemed ineligible for the out patient department shall after being attended to be referred for treatment elsewhere 8 It is inexpedient that any patient be able to leave the hospital without having been seen by a registered medical practitioner 9 The number of new cases seen on one day by an honorary medical officer be limited 10 Special hospitals shall treat only cases strictly within the scope of their work 11 In all hospitals there shall be an age limit for the retirement of medical officers

Address in Medicine

The address in medicine was delivered by Sir William Selby Church He spoke of the advance made in the different branches of medicine since the last meeting of the association at Oxford in 1868 especially in bacteriology physiology and tropical medicine He spoke of the discoveries which have been made in the agglutinative, bactericidal and hemolytic properties of the blood serum, and of the advances which have been made in the field of serum therapy

He spoke of the advance in physiologic knowledge which was attained with the recognition of the connection between myxedema and the diseased conditions of the thyroid gland He also spoke of the internal secretions of other glands such as the suprarenal and in connection with this mentioned the researches of Schäfer and Oliver which have proved the physiologic action of the extract of the suprarenal glands to be both active and powerful

In regard to tropical medicine he spoke of the work which has been done in malaria and yellow fever, the discoveries of Castelani, Bruce and Nabarro in the African sleeping sickness and the experiments of Leishman, Donovan Ross and Christophers which tend to show that the chronically enlarged spleen found in malaria is probably due to some other micro-organism

The active part taken by the association in securing public health legislation and laws regulating the practice of medicine in the British Isles was described He also spoke of the bill which the association has drawn up providing for increased supervision of the sale of foods and drugs the necessity for proper sanitation and hygiene in villages and small towns, as well as in larger cities

He spoke at some length on the necessity for pure air in dwellings and condemned the modern style of architecture which crowded houses and apartments together and did not permit free access of air to the dwellings In conclusion he quoted statistics to prove that the rate of mortality is in direct proportion to the density of the population

Treatment of Chronic Renal Disease.

At the section on medicine Dr Hale White London, spoke on "The Treatment of Chronic Renal Disease" He said that treatment might be divided into the treatment of particular symptoms and treatment employed owing to theoretical views of the nature of the disease He said that albuminuria is often treated, but it is forgotten that the mere presence of albumin in the urine is of itself of no importance except as an aid to diagnosis It is so frequent in heart disease, fevers, etc, that half the patients who have albuminuria have not Bright's disease, yet it is never treated in these conditions Many persons pass albumin in the urine for 20 years or more without harm The loss of proteid in Bright's disease is trifling and can easily be counterbalanced by a little more food Frequently patients are injured by the alarm engendered by frequent examinations of the urine

Diet —A milk diet which is chiefly relied on to reduce the albumin, fails to do so and injures the patient Some patients have a high tension pulse and a hypertrophied heart In such cases the tension must be reduced by restricting exercise, regulating the bowels, avoiding alcohol, meat extractives, excess of meat food and the drinking of much fluid, and in such cases digitalis should never be ordered In another class, where the pulse tension is low and the heart weak, the mistake is made of keeping patients on a limited milk diet in the hope of relieving the kidneys, with the result that the patients become enfeebled and the heart fails, such patients improve on an ordinary diet A patient with chronic nephritis is often injured by starvation Some patients are kept too much in bed and the body becomes flabby On the other hand, acute and subacute cases are not kept in bed sufficiently some take too little exercise and become fat giving the heart more work It is best for patients to drink a normal quantity of fluid.

To sum up, keep vascular tension normal without the aid of drugs Slight edema is best treated by posture, limiting the fluid drunk and keeping the bowels regular The most efficient way to get rid of edema is by Southey's tubes, but antiseptic precautions are necessary

Medicinal Treatment —Such drugs as cantharides must be used carefully blisters are often applied incautiously Drugs which are excreted with difficulty such as lead and digitalis must be given with care As to morphia, small doses are sometimes fatal therefore it should rarely be given Sulphonal and trional should not be given for they may induce hematoporphyrinuria Alcohol in moderate quantities will not injure the kidneys but it should not be given if the pulse tension is high

Granular kidney is frequently treated too zealously, and the patient injured by starvation We do not know for certain that any ordinary article of diet is harmful I give the patient good plain ordinary foods, but exclude sauces and condiments which may possibly cause harm There is nothing to show that red meat is more injurious than white In chronic parenchymatous nephritis similar mistakes are made until the patient loathes his farinaceous diet. His last days may be rendered happier by removing useless restrictions Tea, tobacco and coffee should be used with moderation in consequence of then rendering the pulse irregular Water is given excessively inducing hydremic plethora and injuring the heart

In a few cases of tubal nephritis without edema an extra pint of water may be given daily to wash away the dead epithelium We do not know the nature of the poison in uremia There is a vague belief that it is due to nitrogenous retention, but it may develop on a farinaceous diet The only treatment is to help all the excretions It is of little use trying to stimulate the kidneys Give plenty of hot fluid such as weak tea or transfuse with a saline solution Pilocarpin may do harm Severe convulsions may be relieved by inhalation of chloroform The skin may be stimulated, but excessive sweating should be avoided A warm bath may be given every night

Climate—Egypt is the ideal climate For a few an occasional Turkish bath may be allowed Keep the skin warm by means of woolen underclothing We should not be too quick to check diarrhea and vomiting which may be eliminative It should be remembered that the patients bear operation badly

DISCUSSION

Professor Van Noorden maintained that neither physiologic nor clinical evidence showed that white meat has any advantages over red meat He has found it unnecessary to give great quantities of fluid which injures the heart Systematic muscular exercises are very useful In Germany it used to be the custom to forbid all exercise but more good can be done by the systematic training of the muscles At first the albumin may increase but it then falls to perhaps less than before The great improvement however is in the heart and the sense of health and strength is restored He prefers health resorts where there are carbonic acid baths and saline waters for drinking A most dangerous complication is obesity, which leads to heart failure It should be treated carefully and slowly reduced A milk diet is often harmful by inundating the body with too much fluid

Sir John Moore Dublin pointed out the value of open air treatment as the lungs have an eliminatory function He recommended Sicily as a health resort Oxygen inhalations are useful especially in the so called uremic asthma The drowsiness of uremic coma often yields to 20 grain doses of benzoated soda Urotropin is useful but must be given with care Dropsy often acts as an eliminant The state of the heart is the paramount factor in prognosis Strychnin and digitalis are useful if the heart is failing The tendency of digitalis to raise arterial tension may be overcome by giving it with nitrites or iodids Pilocarpin is a treacherous drug it may ‘drown the patient by the bronchial effusion it induces

Treatment of Tuberculous Pleural Effusion and Pneumothorax.

Dr William Osler Baltimore spoke on the Treatment of Tuberculous Pleural Effusion and Pneumothorax He expressed the opinion that a large majority of all cases of pleurisy with effusion are tuberculous The following are his reasons 1 The postmortem examination in cases of sudden death in pleurisy almost always reveals tuberculosis Even in traumatic pleurisy tuberculosis is often found 2 Healed tuberculosis is often found in patients dying from other causes than tuberculosis 3 Cytologic investigations show the small mononuclear leucocyte almost characteristic of pleurisy Centrifugalization may reveal the tubercle bacillus Inoculation is still more important, and has shown it in 59 per cent 4 There is frequently a tuberculous focus in other parts of the body 5 In a percentage varying from 25 to 35 the patient subsequently becomes tuberculous 6 A characteristic tuberculin reaction has been obtained in a large number of cases

Treatment—For treatment it is best to assume all cases to be tuberculosis For discussion he proposed the value of early and repeated aspiration in acute cases Previously it has been merely an adjunct in treatment Lately there has been a tendency to tap earlier and not to wait for the fever to subside In a large number of cases a cure is obtained In 20 cases treated by him recovery took place in all In some aspiration was performed as often as 4 times Of these cases, 7 were proved to be tuberculous The removal of the fluid sometimes appears to be directly curative It prevents the formation of dense adhesions and certainly does no harm Pneumothorax has followed tapping in a few, but in none of his cases was the pleurisy acute The chronic cases present the most difficulty If tapping fails West's suggestion of incision should be adopted Drug treatment, blisters and the “thirst cure have only a limited field of utility As soon as the fever disappears systematic pulmonary gymnastics should be carried out Careful after treatment to establish the general health is important

The treatment of pneumothorax is very unsatisfactory in consequence of the concurrent pulmonary lesions In a large number of cases it is best to do nothing “*Pneumothorax acutissima*’ demands immediate operation to convert a valvular into an open pneumothorax A group of chronic cases demands the operation recommended by West

DISCUSSION

Dr G A Gibson, Edinburgh, expressed his difficulty in diagnosing tuberculosis He believes that in a large number of cases the diplococcus of rheumatism would be found in the urine He had found tuberculin useful in the treatment of some cases

Mr Stanley Boyd, London, thought that in cases of serous fluid, when repeated tapping failed, it would be best to drain the pleural cavity with a fine canula But he admitted the danger of creating a pyothorax

Dr. Samuel West did not think that tapping materially influenced the course of the case He condemned modified Estlander's operation as futile

Pathologic Chemistry of Gout

Professor Van Noorden spoke on the Pathologic Chemistry of Gout He gave a resume of recent progress and discussed the oxygenation processes the nitrogen metabolism, the influence of gout on the functions of the stomach and intestines, the peculiarities of the absorption of nitrogenous substances and the condition of uric acid in the urine, blood and tissues All these pathologic facts have to be combined in a theory, but are far from sufficient to explain the clinical phenomena He put forward a theory which combines his own, published 12 years ago and a new one recently published by Murkowski

Treatment—Food containing excess of purins should be avoided Alcohol is injurious because it renders the elimination of uric acid difficult and causes retention Remedies which increase the excretion of uric acid must be given Various substances were tested Salicylic acid is apparently the most powerful but it is a dangerous remedy in gout Alkalies are utterly useless though they are excellent in nephrolithiasis In gout they cause retention of uric acid The pure alkalies and Vichy and other mineral waters were tested On the other hand the increase of the renal excretion of uric acid produced by saline solutions and certain saline springs was very remarkable The Homburg Elizabeth spring seemed to be the most powerful Under it the excretion of uric acid often rose from 25 to 30 per cent and remained at this height for a considerable period—a confirmation of an old empiric fact This spring has long been a renowned resort for gout

(To be continued)

ASSOCIATION OF AMERICAN MEDICAL COLLEGES

Minutes of the Fourteenth Annual Meeting held at Atlantic City, N J, June 6 1904

(Concluded from Page 513)

Dr P Richard Taylor moved that the new constitution adopted at New Orleans become operative on July 1 1907 instead of July 1, 1905 Seconded

Dr Means moved that the motion be laid on the table Carried

Committee on President's Address

Dr Egbert, on behalf of the committee on president's address reported as follows

Your committee recommends that the thanks of the association be tendered to President Guthrie for his most able and

excellent address, and that it be printed and a copy sent to each member of the association It recommends further that the various suggestions contained therein be referred to the committee on by laws, with the request that they give the same due consideration and report to the association at an early date (Signed) WM H WATHEN
SAMUEL C JAMES
SENECA EGBERT

Dr Means moved that the secretary be authorized to send to each member of the association a copy of the application blank presented as a part of the secretary's report and that the proper officer shall fill in the necessary data and return the blank to the secretary on or before November 1 1904

Seconded and carried

Dr H B Ward asked for a ruling by the chair with reference to that portion of the report of the special committee on by laws recommending the expenditure of $400 annually for the visitation of colleges Whether the adoption of the report was to be considered authority for the expenditure of the money

The chair ruled that that was the sense of the association that an appropriation for that amount is to be made

Report of Auditing Committee

The auditing committee, through Dr Egbert, reported as follows

Your committee, appointed to examine the report of the secretary treasurer, beg leave to report that they have audited the financial statement, and find it correct They also wish to compliment the secretary treasurer on the fullness of his report, and the important work done by him during the year and that the association tender him a vote of thanks for his efficient services

The report was accepted

Dr J A Dibrell moved that the secretary be authorized to accept resignations from membership Seconded and carried

Dr S C James asked what recourse if any outside of the law colleges have to obtain the admission of their graduates to certain territories of the United States from which they are excluded absolutely at the present time New Mexico bars the graduates of every college in the association except three. They will not permit the graduates from any institution that gives students conditions to enter their territory to practice medicine

No information on this point could be given and the matter was passed

Officers Elected

The nominating committee then reported as follows President, Samuel C James, Kansas City Mo first vice president R. Dorsey Coale, Washington, D C, second vice president R. H Whitehead, Chapel Hill N C secretary treasurer Fred C Zapffe 1764 Lexington Street, Chicago, judicial council, Wm J Means, 715 North High Street, Columbus Ohio chairman, term expires 1907, Parks Ritchie, St Paul, Minn term expires 1907, Geo M Kober, Washington, D C term expires 1906, Thos H Hawkins, Denver, Colo, term expires 1905

Dr Guthrie introduced the president elect, Dr James who addressed the association in a few well chosen words and announced that the next annual meeting would be held Monday June 5, 1905 at the place of meeting of the American Medical Association

The association then adjourned

J R. GUTHRIE, President
FRED C ZAPFFE Secretary

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns The writer's name must be attached, but it will be published or omitted as he may prefer It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in everyday practice Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer]

Gout

Satterthwaite, in the *Med Record*, gives the following method of treating acute gout Elevate the inflamed part and protect from the weight of the bedclothes by a cradle Lead and opium wash may be used, applied on absorbent cotton, covered with oil silk, and renewed every four hours Or a saturated solution of bicarbonate of soda Or

℞	Guaiacol		
	Olei gaultheriæ āā	ʒiv	15
	Olei oliva	℥ii	60

M Sig Apply locally to inflamed part

Or, a more elegant mixture he believed to be

℞	Menthol	℥i	30
	Alcoholis	℥iv	120
	Glycerini		
	Aquæ laurocerasi, āā	℥i	30

M Sig Apply locally to the inflamed part

The patient may be placed in a tub at 98 to 100 F kept there for fifteen minutes, douched with water at 102 F for another fifteen minutes Afterward the flabby parts are massaged and the inflamed parts are left untouched Administer a mercurial purge followed by a saline cathartic The wine of colchicum should be given in from 15 to 20 minim doses every four hours The dose should be lessened as soon as possible because of the disturbance of the gastrointestinal tract, which follows large doses or the prolonged use of the drug Sodium salicylate or salicylic acid should alternate with the colchicum every four hours If the salicylates are not well borne he suggests the citrate of potassium in 30 to 60 grain doses every four hours

Following the mercurial purge he suggests a cholagogue and his favorite is

R	Resin podophyllin	gr ss	03
	Ext colocynth		
	Ext hyoscyami, āā	gr i	06
	Ext nucis vom	gr ss	03

M Ft pil No i Sig One at night if necessary

For drinking purposes he recommends the waters containing carbonate of lime, of soda, of potash, and lithia The diet during the acute stage should be, with the exception of toast and butter, a liquid diet The treatment of the other and more chronic forms of gout consists chiefly in the free use of water, the free evacuations from the bowels, the administration of the iodids and to abort an attack the use of colchicum, the salicylates or the alkaline carbonates The author believes that the patient does better on a dietary of food that he has found to be suitable by personal experience rather than the usual dietary recommended

Luff, in the *London Practitioner*, treats at length on the subject of diet in gouty states He concludes that no routine method can be adopted which is suitable to all cases, but that consideration should be taken of the nutritional conditions of the patient, habits, environs, likes and dislikes, and, as Pawlow has shown that a habit of digesting with ease certain kinds of food is acquired by the stomach which learns to secrete a gastric juice appropriate to it, for this reason certain changes of food may interfere materially with the function of the digestive apparatus A further conclusion is that food stuffs must be used which are not only readily utilized in the system, but must be readily attacked by the gastric juices, therefore the simplicity of meals is more important than the exclusion of certain articles of diet

The following is the diet recommended by Dr Luff for his gouty patients

Morning One half to one pint of hot water, flavored with a bit of lemon peel, taken slowly immediately on rising

Breakfast A selection may be made from the following articles of diet Porridge and milk, whiting, sole, or plaice, fat bacon (grilled), eggs cooked in various ways (never hard boiled) dry toast, or zweiback bread thinly buttered and tea infused for three minutes and strained

Lunch and dinner Vegetable purées, soups made by boiling beef or mutton bones with vegetables and subsequently removing the fat The soups should not be thickened with the farinaceous substances The varieties of fish most suitable are whiting, sole, turbot, plaice, smelt, flounder, gray mullet and fresh haddock The birds that are admissible as articles of diet are chicken, pheasant, turkey and game (not high) Beef, mutton and lamb should be taken at only one meal a day and then in very moderate quantity Two vegetables may be taken at both lunch and dinner, spinach, Brussels sprouts, French beans, winter cabbage, turnip tops, turnips and celery Potatoes may be taken in moderate quantities Stewed fruits, or baked apples, or pears may be taken every day at one meal Green vegetables, as salads, without oily dressings may be allowed A simple savory may be taken at the end of dinner, or a small quantity of cheese, if well masticated and free from molds

Night Half to one pint of hot water flavored with lemon peel should be slowly sipped before retiring

Intestinal Colic

Merck's Archives recommends the following

℞	Spiritus chloroformi	℥ii	60	
	Tincturæ belladonnæ	ʒiiss	10	
	Dionin	gr v		30
	Tinctura cardamon co q s ad	℥iv	120	

M Sig Teaspoonful in water every half hour for adults

Metrorrhagia from Fibroma

Huchard, in the *Med Press*, discusses some of the points in the treatment of this condition from a medical standpoint before operative treatment is feasible.

Hot irrigations with pure boiled water at 113 F, using from three to five quarts, repeated twice or three times daily Compresses of salt water are also to be used A towel steeped in cold salt water (9 oz to a quart of water) is applied to the abdomen and covered with a thick layer of wadding with oiled silk or gutta percha left over all The compress should be kept on at first two hours, gradually increasing the time until it can be borne a whole night The treatment lasts one month and is renewed three or four times a year

For medicinal use he recommends the following

℞	Ext hydrastis canadensis fl	℥i	30	
	Ergotin	ʒi	4	

M Sig Twenty drops three or four times a day or

℞	Hydrastininae hydrochloratis	gr x		65
	Aquae dest	ʒiiss	10	

M Sig Inject one syringe (gr i) two or three days in succession, or

℞	Quinin hydrobromatis	gr ii		12
	Hydrastininae hydrochloratis	gr ss		03
	Ergotin	gr i		06

M ft pil No i Sig Two such pills daily

These pills can be prescribed for ten days The ten following days recourse can be had to cannabis indica or adrenalin The latter has frequently succeeded—ten drops of the 1 to 1 000 solution morning and evening Sometimes accidents occur sensation of anguish and cardiac arrhythmia The treatment should be carefully watched and suspended on the slightest unfavorable symptom

Intestinal Fermentation and Diarrhea

Dr Friedrich Grosse in a communication, gives the following as his favorite prescription for this condition

℞	Bismuthi salicylatis		
	Benzonaphthol		
	Sodii benzoatis aa	gr xlv	3 4
	Syrupi simplici	ʒv	20
	Aquae q s ad	℥iv	120

M. Sig One teaspoonful every three to four hours

In case of diarrhea add or substitute tannigen ʒii (8 grams) for the benzonaphthol in the above prescription

Coryza

Hirtz in *Le Mois Therapeutique* recommends the following dusting powder in the treatment of coryza

℞	Quinin sulphatis			
	Bismuthi salicylatis āā	gr viii		50
	Acidi borici	gr xv	1	
	Amyli	ʒiiss	10	

M Sig Use as insufflation in nose three times daily

Subacute Gastritis

Wood, in the *Therapeutic Review*, discusses the treatment of this condition under the following three heads

Habits—Regularity in the time of eating thorough mastication The value of chewing the food depends not solely on the mechanical subdivision of the mass, but also on the complete ensalivation Salivary digestion in the stomach plays a part hardly secondary to that of peptic digestion

Water—Water should be avoided during meal time as much as possible, it dilutes the digestive secretions, and enables the food to be swallowed without sufficient mastication

Diet—Of the starchy foods those that like toast, stale or pulled bread require considerable mastication are to be preferred Sugar and fats are best reduced to a minimum Of the albuminous foods, well cooked mutton or beef or the fish foods such as rock fish and oysters, are generally permissible Pork, veal and rich game foods should be avoided

Drugs—Stimulation is closely allied to irritation, and where there is a true inflammatory condition the stimulant remedies are always contraindicated such as bitter tonics and stimulating aromatics In cases where there is a marked failure of the hydrochloric acid this drug may be given both on account of its action as a digestant and its antiseptic action

Perhaps even more efficient is the nitrohydrochloric acid which should be prescribed undiluted, since it rapidly deteriorates after dilution Of this, five drops may be given in a half tumbler of water after meals Of the artificial digestants, such as pepsin, pancreatin and the various vegetable ferments the best that can be said of them is that they are comparatively harmless

The one drug which has proved of most value in the writer's experience in the treatment of these cases is the bicarbonate of soda It neutralizes the lactic acid when present, thus relieving the distressing pyrosis, it enables the salivary ferment to act by rendering the gastric contents alkaline, and, finally, it has been most abundantly proven to be one of the most effective stimulants of the secretion of hydrochoric acid It is best given before meals The following prescription has given the author good results where there is much irritation

℞	Bismuthi subnitratis	ʒi	4	
	Sodii bicarb	ʒiii	12	
	Acidi carbolici	gr xv	1	
	Spiritus menth pip	m xx	1	30
	Mucilag acaciae q s ad	℥ii	60	

M Ft emulsio Sig Teaspoonful before each meal

Acute Rheumatism

A Martinet, in *Nouveaux Remedes*, states that a combination of antipyrin and sodium salicylate is remarkably efficacious in this disease On account of the pasty mass it is impossible to dispense in capsules, and, moreover the combination is irritating to the stomach The following is the formula

℞	Antipyrin	gr lxxv	5
	Sodii bicarbonatis	ʒiss	6
	Sodii salicylatis		
	Aquae dest āā	ʒiiss	10
	Rum	℥i	30
	Syrupi aurantii cort	℥v	150

M Sig A tablespoonful as required

Medicolegal.

Liability Between Towns in Contagious Disease Cases—The Supreme Judicial Court of Maine holds, in the case of the Inhabitants of Machias vs the Inhabitants of Wesley, that the right of towns to recover expenses incurred in cases of contagious diseases is governed by statute The fact that the statute gives to the overseers of the poor of the oldest incorporated adjoining town the care of persons found needing relief in unincorporated places does not make such adjoining town liable to reimburse another town for the expenses incured in relieving such destitute person The result is the same if the expenses were incurred by the local board of health

Woman's Charge to Physician Against Man Not Privileged—The First Appellate Division of the Supreme Court of New York says, in the case of People vs Abrahams, where it was sought to fix the paternity of a child born on the 15th of May that a practicing physician with whom the mother had a consultation in the preceding September or October was asked In that conversation, did she make any charge against any person as being the cause of her condition at that time?" This was objected to and the objection sustained It was sought to sustain the ruling on the ground that the answer was not admissible under section 834 of the New York Code of Civil Procedure which provides A person duly authorized to practice physic or surgery shall not be allowed to disclose any information which he acquired in a professional capacity and which was necessary to enable him to act in that capacity" The testimony here sought to be elicited was not information acquired by the physician which was necessary to enable him to act as such It needs no argument to demonstrate such fact and its exclusion may have done great injustice to the accused He testified that he never met the mother until the 15th of October The question called for a statement made by her in September or October and if she stated to the physician at that time that some other person than the accused was the cause of her condition it was possible that the court would have reached a different conclusion than it did adjudging the accused to be the father of the child In any event the testimony was admissible and for the error committed in excluding it a new trial must be had

Expert Evidence on Physical Ability to Commit Crime—The Supreme Court of Alabama says that it understood certain questions asked a physician in the homicide case of Dixon vs State to call for the professional opinion of the witness whether a person suffering from malaria with bilious complications, and in a high fever at 4 p m in the *afternoon* could walk twelve miles and go through the ordeal of killing a man overnight, and be free from fever and of normal pulse early the next morning This was, of course a matter for expert opinion Neither the jury nor the court could know what effect the physical exertion of walking so great a distance and the mental excitement incident to doing murder would have on a man in the accused's condition A physician would know whether such conduct on the part of the accused would likely aggravate his fever over night Assuming an opinion that it would, the fact that the accused had *no fever* the next morning taken in connection with the opinion would be a pertinent circumstance tending to show that the accused had not gone to the victim Gordon's house and killed him It was the same legal question as if it had been shown that the accused was desperately ill on the eve of the homicide—in the last stages of consumption, for instance—and his physician's opinion had been that he could *not have gone to Gordon's, killed him, returned* and himself survived the night and that he was alive the next day Or for further illustration the question stood on the same legal footing as if it had been shown that the accused was critically ill and in a very weak and helpless state and the physician's opinion as to whether he could have walked to and from Gordon's house at all and it seems clear to the court that such expert opinion in either of the cases stated would have *been* competent Therefore it concludes that the Circuit Court erred in sustaining objections to the question calling for the expert opinion of the physician to the effect that the condition of the accused on Sunday afternoon was such that he could not have walked to Gordon's that night and killed him and return to the place where he was stopping and been in the physical condition he was found to be in at 8 o'clock the next *morning*

Court Bound by Physicians' Certificates of Sanity —The Supreme Court of Michigan says that in the case of Grinky vs Durfee Judge of Probate the former petitioned the latter for an order admitting his wife Celia Grinky to an insane asylum At the time set for hearing the judge refused to proceed with the same because two reputable physicians appointed by him to examine said Celia Grinky had reported that she was not insane (One of these reports was not in precise statutory form, but, as it could not be considered a certificate of insanity, its informal character the court says was in its opinion immaterial) Mandamus proceedings were then instituted to compel the judge to proceed to a hearing on said petition an order to show cause was issued a hearing in the mandamus case had and the writ denied In affirming that decision the Supreme Court says that its correctness depended on the construction and effect of Act No 217 of the Public Acts of Michigan of 1903 Section 16 of that act made it the duty of the probate judge, on the filing of Grinky's petition, to fix a date for the hearing thereof and appoint two reputable physicians to make the required examination of the alleged insane person, whose certificate shall be filed with the court on or before such hearing Section 14 of said act provides No person who is a resident of this state shall be held as a public or private patient in any asylum public or private, or in any institution, home or retreat for the care or treatment of the insane except on certificates of insanity and an order for admission as hereinafter provided Section 15 provides Certificates of insanity must be made by two reputable physicians under oath, appointed by the probate court of the county where such alleged insane person resides or is an inhabitant to conduct the examination' Continuing the Supreme Court says that it was urged that notwithstanding the language above quoted, section 16 of the act makes it the duty of the judge of probate, even though the physicians appointed by him certify to sanity to himself determine that question The court can not assent to this construction Under such circumstances a finding of insanity by the probate judge would be a mere idle formality for without the physicians' certificate of insanity the patient could not be held by the asylum authorities The language of section 16 does not indicate the legislative intent to compel the probate court to make an adjudication which would be altogether meaningless On the contrary, the language in that section, above quoted, requiring the certificate 'to be filed with the court on or before such hearing," and the fact that the form of the order therein set forth shall contain a recital of the 'filing the certificates of two legally qualified physicians," indicates to the court that the legislature intended that the probate judge should not proceed when said physicians certify to sanity Nor does the court consider the statute so construed unconstitutional on the ground that the authority of the probate court to make an order for the admission of an alleged insane person to an asylum can not constitutionally be made to depend on a certificate made by non judicial persons It thinks that the most that can be said of such an objection is that the legislature has prescribed a certain rule of evidence, viz it prohibited the making of the order in question unless a certain kind of proof is adduced The authority of the legislature to prescribe this rule might be denied if it deprived any person of a vested right The rule in question certainly does not deprive the alleged insane person of a vested right for it tends to safeguard her rights It deprives no one else of a vested right because it can not be conceived that any one has a vested right to have another committed to an insane asylum Neither does the court agree with the contention that the legislation in question confers on keepers of asylums judicial powers because it prohibits their holding a patient except on certificates of insanity and an order for admission"

1 Recognition and Treatment of Chronic Myocardial Disease A A Stevens
2 Enlargements of the Liver J N Hall
3 *Splenohepatic Fibrosis with a Remarkable Leucocytosis R K Fletcher and S W Sappington
4 *Pathology of Frambesia P G Woolley
5 Subcapsular Nephrectomy for Pyonephrosis Report of Case and Exhibition of Specimen John DeVinne Singley
6 Surgical Aspect of a Case of Jacksonian Epilepsy G Childs MacDonald
7 Treatment of Chronic Internal Hydrocephalus by Lumbar Puncture H Lowenburg

3 **Splenohepatic Fibrosis with a Remarkable Leucocytosis** —The authors report a case of splenohepatic fibrosis in which it was impossible to make a diagnosis owing to the absence of symptoms distinctive of either group The patient, a woman aged 71 had been ill for ten years The left side of the abdomen began to fill up about eighteen months before she sought medical advice The patient also noted a swelling on the right side, but this did not attract her attention as much as that on the left side The abdomen was slightly tender to touch, and the patient complained of a dragging in the lumbar region and a sense of weight and fullness in the abdomen On examination the spleen was traced from the edge of the ribs on the left side downward 9 cm below the level of the umbilicus in the mid clavicular line The tumor was hard and smooth, with a sharp edge The splenic dullness began at about the eighth rib in the mid axillary line On the right side the liver extended almost as far as the level of the umbilicus The liver flatness began at the fifth interspace The organ was firm and smooth The blood count showed the following Hemoglobin, 48 per cent red cells, 4 100,000, white cells, 136,000 The latter consisted of the following varieties Polymorphonuclear neutrophiles, 89 2, small mononuclears, 1 7, large mononuclears, 2 8 eosinophiles 1 4, basophiles 3 neutrophilic myelocytes, 4 5, eosinophilic myelocytes 0 1 There was slight poikilocytosis slight evidence of polychromatophilia, and only a few normoblasts The last blood count, made one month later, showed a marked decrease in both red and white cells and an increase in the polymorphonuclear cells, the others remaining about the same A microscopic examination of the spleen, liver and kidneys showed a diffuse increase of connective tissue The other organs were normal or only slightly

involved Many arteries throughout the body showed the most extreme degree of sclerosis and calcareous change The authors feel that this is a case in which they can not name the cause nor say that the primary lesion was in the spleen any more than it was in the liver The name given to the disease was used simply to indicate the organs clinically and pathologically prominent and to suggest the variety of morbid change present They offer no explanation for the marked leucocytosis in the absence of any complications

4 **Pathology of Frambesia**—Woolley describes the microscopic appearance of a nodule taken from a case of frambesia There was a marked hyperplastic acanthosis with a round celled infiltration of the underlying and especially of the perivascular connective tissues There was some semblance of epithelioma but the acanthus layer of the skin was thickened and prolonged in strands and columns of bizarre shapes In many places in this hyperplastic epithelium there were larger or smaller islands of connective tissue each apparently representing the path of the blood pressure In the centers of such areas and about the vessel were collections of small round cells and plasma cells But this small celled infiltration was most marked in the larger strands of the submalpighian connective tissue Within these areas there were occasional leucocytes and fibroblasts in varying stages of development A number of plasma cells were present within the round cell accumulation At the site of the ulceration the structure of the lesion was modified by the destructive process All the layers were invaded by a multitude of polymorphonuclear leucocytes the blood vessels were widely dilated and there was a certain amount of superficial degeneration There was no distortion of the arrangement of the layers of the skin In many parts of the section a peculiar appearance was noted suggesting the overlapping scales of the fish This was apparently due to the fact that certain of the acanthus cells took a more intense stain on one side in which the nucleus did not participate There were no giant cells no tubercle bacilli no lepra bacilli and no evidence of cell inclusions

8 **Rectal Constipation in Women**—Although this subject is one of the greatest importance Murray believes that it is the least understood and is given the least study It is a question which involves the understanding of diet of occupation of chemistry, as well as the whole process of assimilation, of the mechanical obstructions and inflammatory conditions of the intestinal canal and adjacent structures and the nervous reflex and psychic influences which are more easily recognized in this part of the human system than anywhere else Women are most subject to constipation, especially rectal constipation This may be, but is rarely due to a nervous condition While it may occur as the result of inflammatory conditions such as hemorrhoids, fistulæ and fissures, in very many cases it is mechanical in its origin by reason of the peculiar anatomy of the parts Anteversions, retrodisplacements, neoplasms and periuterine inflammations obstruct the bowel A form of rectal constipation which heretofore has received but little recognition is that which occasions and is the result of the pulling down of the rectovaginal septum, thereby forming a pouch constantly increasing in size, changing the direction of the intra abdominal rectal pressure to that of the vaginal which is at right angles to it, and making it difficult for the rectal sphincters to relax so as to void the contents of the bowel The retention of fecal matter causes rectal irritation and autointoxication In regard to treatment, cathartics may be useful in those cases in which the obstruction is due to inflamed and displaced organs or neoplasms but would be useless in cases where there has been a displacement of the rectovaginal wall In such cases glycerin or gluten suppositories or injections of small amounts of olive oil, glycerin or soothing fluids may be employed The use of daily enemata, as ordinarily practiced, is to be reprehended, from every point of view The use of bougies or dilators may prove beneficial For constipation of purely rectal origin, massage, electricity and measures designed to improve peristaltic action are of no avail The olive oil enemata are especially beneficial The patient, on retiring injects into the rectum the amount of olive oil which can be retained easily during the night The amount varies greatly with different individuals, and with practice one can usually begin with half a cup full, and after a little can retain two thirds or even one cup full The oil is very soothing to the rectum and allays the irritation which has been occasioned by retained feces It is especially beneficial to those who are thin The directions are to take the injections nightly for three weeks, and then every other night for three weeks, and then less often, gradually discontinuing them as may be necessary

9 **Strychnin Nitrate in Progressive Muscular Atrophy**—Brown says that although the hypodermic injection of strychnin nitrate in the treatment of progressive muscular atrophy has fallen short of his expectations, yet it has gone a long way to dissipate the horrible sense of depression, discouragement or even despair, which the prognostic contemplation of these cases hitherto aroused For an adult the dose should be 1/25 gr once daily for six weeks resumed after an intermission of two weeks and so on until several courses have been taken Though many patients can bear a larger dose without exhibiting unpleasant symptoms the results following its use are not so good as when a small dose is given Possibly, a certain amount of the drug might act as a tonic and restorative to the degenerating neurons while more might accelerate the process of decay No other form of strychnin than the nitrate given hypodermically and no form whatever, not even the nitrate itself, given by mouth, can influence the course of the disease favorably The value of hygienic measures, and the judicious use of electricity massage and gymnastics, is rather enhanced than otherwise when used in conjunction with the strychnin treatment

16 *Operations on Benign Diseases of the Stomach F B Lund E P Joslin and F T Murphy
17 The Union of the Teachings in Cystoscopy and Microscopy Frank M Johnson

16 **Operations on Benign Diseases of the Stomach.**—The authors review the surgery of benign diseases of the stomach at the Boston City Hospital and the Massachusetts General Hospital during the last six years They report a series of operations for chronic gastric ulcer, pyloric obstruction and acute gastric dilatation perforation of gastric ulcer and gastric hemorrhage Surgical intervention in gastric hemorrhage should be considered even before it is urgent, and the physician, with the surgeon, should watch the course of the patient Operations on females under 30 years of age should be advised most conservatively since death under medical treatment is rare Time should not be lost during an operation in seeking the bleeding point, but gastroenterostomy should be performed The mortality in operations for perforation of the stomach is dependent chiefly on the length of time intervening between perforation and operation and the virulence of the infection Patients with chronic ulcers of the stomach or strictures of the pylorus should be watched jointly by the physician and surgeon Postponement of operation after it is indicated is dangerous owing to the possibility of hemorrhage perforation and exhaustion Many conditions must be taken into consideration when estimating the final results in the cases reported First, the method used, second the operator, third the time of operation and fourth the nature of the case Doubtless the next six years will show a remarkable improvement in this branch of surgery as compared with the results of the past six years In many instances the technic has been faulty owing largely to the inexperience of the operator Med

ical clinicians are learning to differentiate those cases which are amenable to surgical treatment while there is yet time and opportunity for surgical aid Modern surgical technic, and in particular posterior gastroenterostomy by the method of Moynihan, and the gastroduodenostomy of Finney, have shortened the convalescence and improved the final results in gastric surgery Of the 21 cases of pyloric obstruction operated on 5 died, 9 are well, 3 were relieved 2 required secondary operation, and 4 were not benefited Of the 21 cases of chronic ulcer 5 died, 7 are well, 4 were relieved, 8 required secondary operation, and 5 were not relieved Hemorrhage—Ten cases 10 deaths Perforation—Eighteen cases, 13 deaths 5 recoveries and 2 cases required secondary operations Acute dilatation—One case, 1 death

19 *The Best Method of Operating to Effect a Radical Cure of Senile Hypertrophy of the Prostate Gland (To be continued) Orville Horwitz
20 *The Indications for and the Technic of Prostatectomy G Frank Lydston
21 Appendicitis Associated with Disease of the Tubes and Ovaries H C Coe
22 *Placenta Previa Centralis A A Moore

19 **Senile Hypertrophy of the Prostate**—As the result of a study of 150 radical operations for the cure of senile hypertrophy of the prostate gland, Horwitz concludes that a Bottini operation or a prostatectomy performed as soon as the symptoms of obstruction begin to appear offers the individual a better chance for help, comfort and prolongation of life than the unfortunate patient who leads a catheter life Experience proves that patients of the latter class eventually succumb to one or the other sequela attendant on this method of treatment The author advocates early operations in both private and hospital practice, and reproaches himself for being at times too conservative by delaying surgical intervention He urges on the profession the importance of having a surgeon supervise these cases of prostatic hypertrophy in conference with the attending physician as soon as it is deemed necessary to resort to catheterism By adhering to this rule cases that will ultimately require an operation will be recognized early and permanently relieved with comparatively little risk If this suggestion were followed the mortality attendant on radical operations would drop to a very low percentage and so-called "palliative operations would seldom be resorted to The Bottini operation often is condemned by an individual whose experience is limited to a few operations possibly in cases the majority of which may not have been suitable for such an operation And a certain procedure is advocated based on the report of a few successful cases Such expressions of opinion are valueless, as reliable statistics can only be obtained by the study of the results in a large number of cases Furthermore no effort is made by writers to classify their cases according to age, character of the growth condition of the patient or length of time that he has suffered, all these conditions have a direct bearing on the proper methods of treatment, the results which follow the operation, as well as the question of mortality Of all the radical methods that have been suggested for dealing with enlargement of the prostate gland, but two have stood the test of experience—prostatotomy by means of the galvanocautery (the Bottini operation) and prostatectomy

20—See abstract in THE JOURNAL xli, p 1106

22 **Placenta Previa Centralis**—Moore reports a case of placenta previa centralis in which there were very copious hemorrhages, followed by collapse It was impossible to find the edge of the placenta, so that it was deemed expedient to introduce the hand directly through the placental tissue this in the author's opinion, being less likely to produce violent hemorrhage during the ensuing manipulations than if the placenta were stripped from the uterine wall Podalic version was performed, the placenta was delivered manually Credé's method proving ineffectual The child was dead The patient was given a hot mercury bichlorid intrauterine douche, 1 to 10,000, at a temperature of 112 F One half a dram of fluid extract of ergot was given hypodermically, and this was continued three times on the following day and twice on the next On the third day the patient's temperature was normal, and continued so until the eighth day, when the patient was discharged from the hospital Moore believes that the fetus had died one or two days before its delivery, as there was a minus quantity of the normal mucus in the mouth and throat, and in efforts at insufflation by the mouth there was no mucus blown out of the nose

27 Puerperal Sepsis Swithin Chandler
28 Vaccination and the Law Nelson G Richmond
29 Dipsomania and Its Treatment William Lee Howard

25 ***Gastroptosis**.*—Kemp details the result of a series of observations made on cases of gastrointestinal diseases in two New York hospitals He calls attention to the unfortunate fact that too often physicians depend on the examination of the stomach contents alone for a diagnosis of gastroptosis, and neglect the investigation of the motor functions and position of the stomach A prolapse of the stomach may exist without discoverable nephroptosis, and often with no enteroptosis that is detectable by the ordinary means of physical diagnosis As long as the functions of the organ are normal we can not regard the conditions met with as pathologic He discusses atonia gastrica dilatation of the stomach and gastroptosis the general treatment of the latter being summed up as follows 1 Correction of the derangement of the stomach by appropriate diet and medication suited to each case 2 Regulation of the bowels 3 Mechanical support to increase the intra-abdominal tension such as (a) silk abdominal supporters, (b) bandaging as by the Van Valzah Hayes method, (c) Gallant's corset, (d) Rose's adhesive plaster belt—the best of the three as it can not slip and become displaced He prefers, however, rubber plaster on moleskin, as it is looser in texture and the sweat readily evaporates through it It can be worn longer and with practically no irritation It is superior to the ordinary rubber adhesive and even to the zinc oxid plaster Dr Rose's belt is the best to fulfill the indications The paper closes with a description of the various methods that may be employed for locating the position of the stomach

26 ***Collargolum and Antistreptococcic Serum in Eye Infections***—According to the authors 7½ per cent of the blind are made so by injuries to the eye and the ineffectiveness of modern methods of treatment This has led them to conduct experiments with collargolum and antistreptococcic serum with the view of determining their efficiency in the treatment of infected wounds of the eye Collargolum is an allotropic form of silver (colloidal silver), which is soluble in water in the proportion of 1 to 25, forming a brownish solution It has some direct bactericidal action and produces a marked and rapid leucocytosis, but is ineffectual in preventing the spread of purulent processes in the eyes of rabbits, whether used intravenously or by injection into Tenon's capsule. It has, however, been used with considerable success in septicemia and pyemia, surgical infections, puerperal sepsis, sepsis of infectious diseases, skin diseases, venereal diseases and certain muscle diseases, including rheumatism, abscesses cellulitis, etc when injected intravenously in a 1 per cent. solution It has also been used successfully by inunction in the form of Credé's ointment in the treatment of eye diseases In the experiments a 2 per cent solution of collargolum was injected, in one series of animals into the veins, and in another series into the capsule of Tenon Twenty five minims of the solution were injected into the veins on successive days, but the inflammatory conditions increased The same was true of the second series that in which the injection was made directly into the capsule of Tenon In still another series collargolum in 100 minim doses of the 2 per cent solution, was injected intravenously The results were the same as in the other

eries In another set of experiments antistreptococcus serum was injected intravenously in quantities varying from 5 to 10 c c The injection of the serum into the capsule of Tenon also was ineffectual Antistreptococcus serum does not appear to exercise any favorable influence on purulent processes in rabbits eyes, but there is no good reason why serum treatment should not be tried in all forms of purulent eye diseases inasmuch as it has been found successful in the treatment not only of pure streptococcus infection, but also of such infections mixed with staphylococci The use of antistreptococcus serum, being harmless, may be of benefit even though selective in its action In certain experiments it has been shown that the doses of serum must be increased enormously the longer the treatment is begun after the primary infection The authors recommend the exercise of considerable care in its use as death is likely to follow from air embolism, as was the case in one of their experiments

35 *Modification of Cow s Milk for Feeding in Early Infancy McGuire Newton

35 **Modification of Milk for Infant Feeding**—To those who live in large cities, says Newton, the modification of milk is an easy task, but for those who have not the advantage of a milk laboratory, and who, consequently, have to resort to the home modification, there are many difficulties, and these are often sufficient to prevent an intelligent attempt to prepare a proper food mixture A number of set formulæ may be used, but that based on an analysis made for winter is the simplest and will be of much service in overcoming the difficulties connected with the modification of milk The formula is as follows

INFANT S AGE	TABLE 1			TABLE 2				TABLE 3	
	Percentage of Fat	Percentage of Sugar	Percentage of Proteid	Quantity of "top milk" from a vessel containing a quart (in ounces)	Milk Sugar (in teaspoonfuls)	Lime Water (in ounces)	Boiled Water (in ounces)	Number of Feedings	Amount of each Feeding (in ounces)
1-3 day	2	7	0 25	1	3 5	1 5	9	10	5-1
4-7 day	2 5	7	0 33	1 5	4	2	10 5	10	1 1 25
2d week	3	7	0 50	2 25	4	2	10	10	1 5
3d week	3 5	7	0 75	6	7	4	18	10	1 5-2 5
2d month	4	7	1	9	8	4	19	9	2 5-3
3d month	4	7	1 25	11	7 5	4	17	8	3 -4
4th month	4	7	1 50	13	7	4	15	7	4 5-5
5-6 month	4	7	1 75	15	6 5	4	13	6	5 5-6 5
7 9 month	4	6 5	2	17	5 5	4	11	6	6 5-7 5
10-11 month	4	6	2 50	21	4 5	4	7	5	8 -9
12 month	4	5 5	3	25	3	4	3	5	9 -10

In the first table will be found the proper proportions in which the constituents should occur at the various ages In the second table are found the quantities of "top milk" sugar, lime water and sterile water necessary to prepare proper mixtures, and in the third table are found the number of daily feedings and the quantity of each for various ages To prepare food mixtures according to this table, it is necessary to have a quart of milk which has stood long enough for the cream to rise, and from which the desired quantity is to be taken by means of a dipper or siphon made for the purpose. The formula is simple and accurate, and when the table is followed closely mistakes are much less liable to occur than with a more complex method Certain indications demand special modification of the milk, such as a slow gain in weight with no digestive disturbance, indicating a deficiency in all the ingredients, especially the sugar Thin, green, acid stools, with or without colic, indicate an excess of sugar Constipation, with dry, hard stools, indicates a deficiency in fat Excess of fat will cause vomiting or regurgitation of small quantities of food one or two hours after feeding, or frequent, apparently normal, bowel movements The presence of curds in the stool, with or without colic, points to an excess of proteids These indications are to be met by the use of formulæ in which the disturbing elements are altered in response to the demands of the case

The Laryngoscope, St Louis

36 Reflex Neuroses of Nasal Origin G Hudson Makuen
37 Neuroses of the Pharynx F E Hopkins
38 Neuroses of the Larynx Emil Mayer
39 *Some Interesting Cases of Mastoiditis James F McCaw
40 *Treatment of Tinnitus Aurium Wm S Bryant.
41 Unilateral Hyperasthesia of the Tongue as a Concomitant of Acute Otitis Media Lennox Wainwright.
42 Chevalier Jackson s Transilluminator with Some Modifications Otto T Freer

39 **Some Interesting Cases of Mastoiditis**—The first case reported by McCaw is one of acute suppurative otitis media, mastoiditis, subperiosteal mastoid abscess and perisinus epidural abscess following scarlet fever The interest in this case centers about the fact that, although rupture had taken place through the external surface of the mastoid, serious involvement of the intracranial contents was taking place It furnishes a striking illustration of the necessity of always opening the mastoid process in subperiosteal accumulations, regardless of the fact that the external surface may show no pathologic changes The patient was operated on and recovered The second case was one of acute suppurative otitis media and double mastoiditis, following an attack of influenza. The points of interest in this case, besides the simultaneous occurrence of a double mastoiditis, were the profound septic conditions and mental derangement The third case contracted acute suppurative otitis media and mastoiditis following typhoid fever Although there was some uneasiness in the ear for about one week, it was only three days after the first pain in the ear before operation revealed an extensive mastoid involvement There must have been a simultaneous infection of tympanum and mastoid, as the extensive distribution of pus and the beginning necrosis can not be accounted for in any other way The anomalous arrangement of the cells about the mastoid tip also was a peculiarity in this case. The most internal one was situated so deeply that it might readily have been overlooked and continued to act as a focus of infection. In the last case, one of acute suppurative otitis media, mastoiditis, epidural abscess and meningitis, there was no history of a previous illness, except that the patient a man aged 87, had been almost totally deaf in one ear for twenty years The diagnosis was evident but in view of the patient's extreme age, the complications and the request of the family, operative measures were desisted from at that time When the operation was finally performed the patient died, without regaining consciousness, forty eight hours afterward with pulmonary edema

40 **Treatment of Tinnitus Aurium**—Bryant gives a very thorough review of the local treatment of tinnitus aurium from all causes, and presents the following classification

I OBJECTIVE.
  1 VIBRATORY
  1 *External* (a) Vascular (b) Pharyngeal (c) Respiratory (d) Muscular
  2 *Internal* (a) Tubal (b) Tympanic
II SUBJECTIVE
  (A) PHONETIC

  3 *Sensory* (a) Nerve Tinnitus I Peripheral II Trunk III Proximal IV (b) Psychopathic I Central II Illusional III Hallucinational IV Delusional

supply for a household or town, would be entirely unsatisfactory It is unsuited for domestic purposes, and is even more objectionable for generating steam because of its tendency to oxidize metals, and in that way to destroy apparatus The chemistry of good drinking water is discussed at great length, it is the same as can be found in any modern text book on the subject For the filtration of surface waters used in the household the author recommends filters made of unglazed porcelain or fine infusorial earth, such as the Pasteur and Berkefeld filter The latter is superior to the former, as it filters considerably faster Of course, all filters require frequent and thorough cleansing It may be necessary to sterilize or distill the water or to purify it chemically Of the method instituted for the chemical purification of water, the most successful has been the use of ozone, generated electrolytically and passed through the water Traube's method, the addition of chlorinated lime or bleaching powder, is also a good one For general domestic use no water requiring treatment is to be recommended, first, because of the expense involved in securing the required purification, and secondly, because of the danger through carelessness or neglect of not being able at all times to maintain a proper standard of purification The capitalized cost of maintaining a purification system generally will more than suffice to provide a supply of wholesome water Having procured a satisfactory supply of water for domestic use, it is necessary that such constructive measures shall be taken as will enable the water to be transported from its source to the place of utilization without impairing its quality, and of storing it in sufficient quantities for all ordinary uses or emergencies

72 *Mastoiditis in General Practice J A Stucky

72 **Mastoiditis in General Practice** —Stucky is of the opinion that the average practitioner does not appreciate the gravity of suppurative disease of the ear, nor equip himself with the facilities for recognizing serious complications, either in the acute or chronic forms The average case of chronic otorrhea can not be wiped out or medicated into a healthy condition Mastoid antrum disease is the appendicitis of the head, and every case of chronic suppuration of the middle ear is a slumbering volcano or a charge of dynamite liable to explode at any time The only safe treatment for suppurative mastoiditis is an early opening of the cells and the establishment of free drainage, thus getting rid of the disease entirely, or else making it the point of least resistance from the brain in case of subsequent infection Under aseptic precautions the operation is practically devoid of danger, delay in doubtful cases may lead to more serious complications When in doubt whether there is pus formation, if there be evidence of mastoid involvement, it is safer to do an immediate exploratory operation rather than to attempt to abort the disease In no diseases are the symptoms more misleading than in the one under consideration Pain, temperature, and pulse, and general systemic condition often do not give evidence of the serious destruction of tissue and rapid inroads being made on the vital centers The auditory canal should be examined thoroughly, and any sagging or bulging of the posterior superior wall is to be regarded as pathognomonic evidence calling for immediate operation Pressure, which causes pain over the antrum or tip of the process after the third or fourth day of an acute otitis media in which there is a free drainage through the tympanum with systemic disturbance, is also an indication for surgical interference The consensus of opinion is that it is eminently wise to operate on cases of chronic suppuration in the quiescent state Then the Stacke operation can often be done, involving a short convalescence There is always danger in delay, but, perhaps, never more so than in the acute stage of mastoiditis when involvement of important structures may be very rapid and often fatal

12 Case of Acute Arsenical Poisoning R L Sedgwick

8 **Red Light Treatment of Smallpox** —The authors report a series of 13 cases in which the red light was used without any benefit to the patient The ward in which these cases were treated was a small one containing four beds It has six windows, all of which were blocked by a double layer of photographic ruby" fabric There were two doors, over each of which was hung a curtain made of a double thickness of red "Turkey twill' The doors opened into lobbies, and an area around each door was screened off with a double thickness of the same material, so that on passing through the door and under the door curtain one found oneself in a small chamber completely shut in with red curtains The effect of this arrangement was that persons entering or leaving the ward admitted no white light when raising the curtains In fact, the ward was converted into a photographic dark room Artificial light was obtained by the use of dark room lamps with red glass Of the 13 cases treated in red light throughout the period of suppuration, 5 were vaccinated, 6 were unvaccinated, 1 patient had been vaccinated in the period of incubation, and in 1 case the matter was doubtful Four were cases of discrete and 9 of confluent smallpox The mildest case was one of a very moderate type of discrete smallpox, and at the other extreme was one of very severe confluent smallpox Two of the patients died, both during the fever of suppuration In neither case was there any complication to which the fatal result could be attributed The treatment did not affect suppuration nor did it prevent scars The milder cases recovered without scars and the more severe did not The authors agree that this treatment possesses none of the merits which have been claimed for it, in fact, the mental complications occurred more frequently and were more severe than with the ordinary methods of treatment. In most of these cases the treatment was harmful In addition to increasing the tendency to mental symptoms, the suppurative fever appeared to range higher than might have been expected, and the general condition of the patient was bad The patients did well in respect to affections of the eye, as might be expected, but they had more than their share of the other septic sequelæ of smallpox One great objection to the red light treatment is the difficulty of carrying out personal and general hygienic measures, because in excluding light we must necessarily limit the supply of air In all suppurative conditions, and especially in smallpox, an abundant air space and the freest circulation of air is essential Any form of treatment which puts a check on the supply of fresh air must be regarded with suspicion unless it brings solid advantages in compensation, which is not the case with the red light treatment The writers appeal to Dr Finsen to cease to lend the weight of his authority to the support of a method of treatment which, if it is inefficacious, necessarily must be inhumane

11 **Multiple Sarcoma** —Taylor reports the case of a man aged 32 the victim of multiple sarcomata Scattered over the abdomen and thoracic walls were a number of solid tumors varying in size from that of an orange to that of a large pea The large growth was situated on the right side of the abdominal wall midway between the anterior superior iliac spine and the umbilicus Its surface was red and granular, but there was no discharge, although yellowish scales of necrosed epidermis appeared between the granular nodules Both mammæ were indurated and involved with the neoplasm Similar nodules were found in the skin over each fourth costal cartilage, and gave the impression of a circular outbreak involving the abdominal wall principally, but also the lower zone of the thorax but to a lessened degree Smaller growths were found over the front of the upper chest. The inguinal and axillary lymph glands were indurated and matted together Those of

the neck were unaffected The skin was fully movable over each tumor and was uninvolved over the smaller ones Similar tumors were also found on the back, especially over the left scapula All these growths appeared within a period of six months Microscopic examination showed these tumors to be small round celled sarcomata The patient died seven months after the first signs of the disease were noticed No autopsy was allowed

21 Syphilis in Children George F Still
22 The Ocular Manifestations in Syphilis and Their Treatment Walter H Jessop
23 Syphilis and its Treatment in the Upper Air Passages St Clair Thomson

14 **Mercurial Injections in Syphilis**—Wickham says that the hypodermic method has the great advantage of sparing the stomach, it favors the more direct penetration of the mercury into the blood stream, a more complete utilization of the dose administered, and permits of exact dosage Before undertaking the treatment, it is well to examine the urine with reference to the condition of the kidneys, and to insist that the teeth be thoroughly overhauled by a dentist If the state of the kidneys is carefully watched and the cleanliness of the mouth maintained, large doses of mercury can be taken without inconvenience The initial dose should be small, and then raised gradually, but persistently, as long as no reaction is produced The surgeon should inform himself of the exact mercury content of the salt he elects to use It is well to restrict one's medical armament so that by employing only a small number of preparations we may become thoroughly familiar with the mode of using them It is best to raise the dosage to a considerable amount rather than to use a moderate average dose, which may prove quite insufficient in particular instances It must be remembered that an attack of syphilis which at first appears benign may develop into a grave case In cases of gravity it is natural to employ large doses, but every case must be looked on as potentially grave and treated as such Along with the treatment by injections all collateral remedial measures must be carried out, such as local dressings and tonics, these measures are of the greatest importance and may in some cases assume a dominant position In cases where the weakness of the patient is marked, injections of mercurial salts incorporated with large doses of physiologic serum are excellent, although the injections of the serum in large quantities apart from the daily injections of soluble salts of mercury are preferable The best site for the injection is the buttock, at the point of intersection of two lines, one horizontal line passing through the junction of the upper quarter with the lower three quarters of the buttock, the other a vertical line through the junction of the internal third with the external two thirds of the region The injections can be made in an area having a radius of 2 cm., the point of intersection of the two lines being its center The injections may be either superficial, or they may be deep, because of the irritation produced by salts of mercury, the injections are almost always intramuscular In thin subjects, in whom gluteal intramuscular injections are not well borne, and in whom it is necessary to attack the disease vigorously, the intravenous route may be chosen The injections may be given at the bend of the elbow into the cephalic or basilic vein on either side The usual antiseptic precautions must be observed The salt used is a cyanid, the largest dose hitherto employed being 0 01 gram daily The author also discusses the instrumentation, the different mercurial solutions preparations of insoluble salts and gives directions for treatment and the choice of salt to be used

17 **Zittmann Treatment of Tertiary Syphilis**—Cases are occasionally met with in which iodid or mercury not only prove ineffectual in arresting the progress of the disease, but actually aggravate the symptoms and hasten the destruction of tissue It is in such cases as these, says Cooper, that the Zittmann treatment proves most effectual Under it healing occurs rapidly, and the symptoms disappear quickly A fortnight's treatment with this remedy will arrest the disease and will cause rapid healing and cicatrization of the lesions The principle of the treatment consists in eliminating the poison from the system by sweating and purgation The patient is kept in a room the temperature of which is maintained at 80 F The evening before commencing the treatment two of the following pills are administered

℞	Hydrarg chloridi mitis	gr ii	12
	Ext colocynthidis	gr v	30
	Ext hyoscyami	gr ii	12

The diet is regulated, and for the first four days the patient drinks half a pint of the following decoction, as hot as possible, at 0, 10, and 11 a m , and 12 m

DECOCTION I

℞	Rad sarsæ contus	iv	
	Sem anisi contus		
	Sem fœniculi contus, āā	ʒviiss	31
	Fol sennæ	℥i	30
	Rad glycyrrh contus	iv	
Add	in a linen bag		
	Sacchar alb		
	Alum sulph		
	Hydrarg chloridi mitis, āā	ʒiss	6
	Hydrarg bisulph rub	℈i	1
	Aquæ	Cong iii	12 liters

Boil gently down to 1 gallon, strain, and put into four 40 ounce bottles

On the same days, at 3, 4, 5 and 6 p m , half of the following decoction, which is taken cold

DECOCTION II

To the dregs from No 1 decoction add

Rad sarsæ contus	℥ii	60
Cort limonis contus		
Sem cardamon contus		
Rad glycyrrh contus , āā	ʒi	4
Aquæ	Cong iii	12 liters

Boil gently down to 1 gallon and put into four 40 ounce bottles

The patient is kept in bed except for an hour every evening, when he may sit up On the fifth day he is given a hot bath and allowed to get up In the evening two pills are administered, the patient starting the decoctions again on the next day as before This treatment goes on in the same way until the fifteenth day, when it is discontinued The author has used it with great success in all the tertiary lesions of syphilis, as well as in many skin diseases and in rheumatic and gouty affections

19 **Serum Treatment in Syphilis.**—The results of this treatment, says Lane, have not been sufficiently favorable to recommend it as a routine therapeutic measure The majority of cases treated with serum showed some improvement in the general health and a more rapid healing of the syphilitic ulcers, especially when other anti syphilitic treatment was used concurrently Nevertheless, the treatment does not appear to modify the course of the disease or to diminish the intensity of the later manifestations

27 Peritonitis or Ileus Charles MacLaurin
28 Conservatism in Renal Surgery H C Hinder
29 *A Case of Unilateral Gigantism C Reissmann
30 *Ethyl Chlorid as a General Anesthetic St John Dansey

29 **Unilateral Gigantism.**—Reissmann reports the subsequent history of a case of unilateral gigantism which came under his observation in September, 1902, and was reported at the time The patient, a child 26 months old, still exhibits right sided gigantism, the cheek, arm, forearm, and leg and

foot on the right side are larger than the corresponding parts on the left side, but not as much as they were 20 months ago The giant side has not grown proportionately to the sound side, although it is stronger The head is large for a child of its age, but the left side of the cranium, in the parietal and occipital regions, is larger than the right The child speaks well, is intelligent, active and strong, but irritable The peculiar interest in this case lies in the association of left cranial enlargement with complete right sided gigantism No similar case has been reported The author suggests that some part of the central nervous system (? the left parietal cortex) is primarily at fault It is a noteworthy fact that none of the 11 reported cases of gigantism were observed until some time after birth In the case in question nothing was noted amiss with the child until it was some weeks old, from which one may conclude that the overgrowth of tissues did not commence until after the nervous system has established what the author terms trophic control over the peripheral tissues If the condition of gigantism is due to an abnormality of the developing mesoblasts, as has been suggested, it is remarkable that not one of the 11 recorded cases were noticed at birth Reissmann believes that there is sufficient evidence to warrant a strong suspicion that the origin of this rare condition is a pathological activity of certain nervous structures which excites an abnormal growth in the parts they control In the case in hand it seems probable that the nervous structures primarily affected are those which have some influence on the growth of the right side of the body, namely, the cortical cells in the parietal region of the left side of the brain

30 **Ethyl Chlorid as a General Anesthetic.**—Dansey prefers ethyl chlorid to nitrous oxid gas because it is quicker in the initiation of anesthesia, there is none of that disturbing duskiness which is more the rule than the exception with the administration of gas, it gives a much longer narcosis, the apparatus necessary is more easily portable and the ethyl chlorid is cheaper, it is not unpleasant to the patient, the recovery from narcosis is rapid and there are no subsequent ill effects ethyl chlorid is stimulating to the circulatory and respiratory centers, rather than depressing He has given ethyl chlorid in over 60 cases for removal of adenoids, opening abscesses, teeth extractions, exploratory punctures, etc He uses an ordinary Clover's ether inhaler, the ebony plug at the side being replaced by one with a small hole eccentrically placed downward, into which fits a small conical peg The usual rubber bag is used or a bag made of fine silk lightly wrung out of water To fill the inhaler the indicator is turned to zero and the small peg removed, through this hole about 4 c c. of ethyl chlorid are sprayed into the ether reservoir The patient is told to take a deep breath and the mask is fitted to the face in the usual way At first the pulse is slightly slowed, but it soon regains its former rate, the color is good right up to deep narcosis, spasm and excitement are very rare When the pupil is well dilated and the conjunctival reflex has disappeared the patient is anesthetized sufficiently In anesthetizing with ethyl chlorid the chief point to bear in mind is the very rapid transit through the second and third stages of anesthesia. He also uses ethyl chlorid to initiate the narcosis of ether

37 *L étiologie de l appendicite grippe et alimentation carnée (meat diet) J Lucas Championnière
38 Cas d épithélioma cutané de la region temporo-frontale, guéri par application des rayons X. C Monod.

31 **Anti Cancer Campaign in the Country**—Triboulet urges the installment of Röntgen apparatus in small towns for free, or nearly free, treatment of the poor in the outlying farm district. In certain of the French provinces the number of cases of cutaneous cancer is very large—no village is without a few—and they could so easily be cured under Röntgen treatment if it were only accessible at moderate cost

32 **Cure of Tongue Lesions by Radiotherapy**—Bisserié relates that two rebellious cases of epithelioma of the tongue were completely cured by the Röntgen rays in less than two months, one with four exposures, the other with three Three months have since elapsed without recurrence and the lesions are apparently cured Another patient who had suffered for eight years from fungoid mycosis was practically cured by a few exposures, as also others with leucoplasia of the tongue

33 **Pancreatic Diabetes, Its Lesions and Nature**—Lancereaux describes 4 cases of the type he calls "thin diabetes" Large amounts of sugar were eliminated, 500 gm in the twenty four hours in one case with 5 liters of urine, about 90 gm to the liter in the second, with 12 to 15 liters per day, in the third, 750 to 1,100 gm sugar in 6 to 10 liters, and in the fourth, with a maximum of 550 gm sugar in about 5,500 c c. of urine All the patients were extremely emaciated and they wasted away in progressive debility to death in coma after two to several years Diabetic symptoms, polydipsia, polyuria, polyphagia, etc, the discoloration of the lips, dryness of the skin and weakness were common to all the cases, and at the necropsy all the islands of Langerhans were found completely destroyed The acini were affected in some parts, not in all, but the constancy of the lesions of the islands of Langerhans confirms the connection between them and the disease It is possible that some direct or reflex nervous inhibition from these islands of Langerhans may be the cause of the other types of diabetes, the nervous and arthritic types In all these conditions the diabetes is the symptomatic expression of some functional or material disorder of the nervous system or of some alteration in the pancreas of variable origin Diabetes should, therefore, be regarded as a mere symptomatic expression of the more or less advanced degree of annihilation of a special organ.

34 **Notes from a Children's Sanatorium.**—Vidal has been collecting data in addition to his own experience, which show that girls are much more subject to tuberculosis than boys, and also to all respiratory affections On the other hand, he noted that boys were more subject to parasitic scalp affections than girls A number of local epidemics of favus, alopecia areata and tinea circinata have occurred among the boys, but not among the girls, and the epidemics could not be arrested until the hair of the boys was allowed to grow long Evidently long hair protects against these affections, and possibly, also, pomades applied to the hair

35 **New Anesthetic Stovaine**—Reclus has been testing a new analgesic made by synthesis by a French chemist, Fourneau, and states that now, for the first time, we have in our possession a substance fully the equal of cocain, while only half as toxic and very much less expensive It exerts a specific tonic action on the myocardium Billon, Pouchet and others have also been testing it on animals and in the clinic, and emphasize in particular its special tonic action on the heart Stovaine is the hydrochlorate of benzoic ether of dimethylamino propanol, and is not a general anesthetic Not a trace of by effects was observed or elicited by questioning in the clinical cases in which it has been used for local analgesia, epidural injections, etc

36 **Gelatin Treatment of Aneurisms**—Lancereaux was the originator of this method of treating aneurisms, and here reports his experiences during the years he has been using it Gelatin injected into the buttocks is carried into the blood, and wherever the current is sluggish and there is a depression, an eddy, in the channel, fibrin is deposited. This ensures clot formation in the depths of the aneurism, exactly where it is needed. In the thousands of injections made in his service there has not been a single mishap If any have been observed by others they are due exclusively to impure material or defective sterilization He relates the clinical history of 8 cases of large aneurisms of the aorta treated in this way, 4 of the patients are in good health to day All pains ceased after the first injections, and the tumor subsided. The aneurism was so large in 2 instances that a fatal result was inevitable—

the skin mortified from the pressure of the tumor—but the gelatin relieved the patients and the clots in the pocket prevented rupture, the final hemorrhage being merely an oozing instead of sudden gush of blood Two patients succumbed to sudden syncope before the benefits of the gelatin treatment were apparent The 4 others have been relieved of all their pains and discomfort, and the tumor has vanished No other method of treatment can show such good results in 50 per cent of the cases He used a solution of 7 gm of sodium chlorid and 25 gm of gelatin, with water to make 1,000 gm The formula for a single injection is generally 5 gm gelatin in 250 c c of a 7 per 1,000 salt solution He injects 200 gm every three or four days (At first he made the injections only once a week, but found that the intervals could be safely shortened) Occasionally the injection caused a slight febrile reaction, or a little inflammation at the site, but these accidents were always briefly transient The injected fluid is completely absorbed in less than twenty four hours He sterilizes the gelatin under pressure at 105 to 115 C the latter temperature being the one accepted as preferable by the Academie

37 **Etiology of Appendicitis**—Lucas Championnière denies that appendicitis has long existed and merely passed unrecognized He attributes it to the epidemic of grip, affecting persons who habitually eat much meat He regards appendicitis as a new disease, and advocates restriction of the intake of meat as important in prophylaxis, as also periodical purges Purgation is the great preventive of all alimentary infections, and it should rank as the chief means at our disposal to ward off appendicitis Occasional fasting from meat is an excellent measure, especially for those who have suffered from grip He groups a large number of facts collected from various sources to sustain these views Among them we note the first appearance of appendicitis in certain localities, always after an epidemic of grip, the latter being followed by numerous cases of the previously unknown appendicitis He cites letters from physicians practicing in tropical regions, all testifying to the absence of appendicitis among the vegetarian natives, and its occurrence among the meat eaters In Roumania, whenever there is an epidemic or a sickly period at any remote point in the country, a detachment of physicians and nurses is sent from the hospital of the capital and a temporary hospital is set up, a sort of annex to the large central hospital at Bucharest, and under the control of its officers Professor Stoicesco is at the head of this unique service, and he states that in the rural districts, where little or no meat is eaten, no cases of appendicitis are encountered Out of 108,651 patients treated in these rural hospitals, 1898 1902, only 5 cases of appendicitis were observed, or once in 22,000 patients In the hospitals of the city of Bucharest, during the same period, 221 cases of appendicitis were observed in the 51,817 patients, a proportion of once in 234 patients *La grippe* has swept over the country as over the towns, but the population in the country is vegetarian, while in the towns meat is eaten In the French, British and other colonies and armies the same observation is made again and again, the absence of appendicitis among the native non meat eating population and its prevalence among the meat eaters In the French prisons meat is allowed only once or twice a week, and no eggs In the asylums, also, the menu is essentially vegetarian None of the physicians interrogated knew of a single case of appendicitis in some of these institutions and in the others only 3 cases in many years, one of these a recurrence in a new inmate Investigation of the religious orders showed a remarkable absence of appendicitis among those whose vows compel abstention from meat or frequent fasting, while in others, where much meat is used, appendicitis is remarkably frequent

44 Importance of Daily Weighing of Patients with Anasarca. J Courmont Abstract

39 **Debility from Persisting Lacteal Secretion**—Cheinisse warns that it is possible for the secretion of milk to persist indefinitely in a more or less latent stage and seriously compromise the general health He has observed a case of this kind in which there was pronounced debility and anemia in a young, previously healthy primipara, who had weaned her child more than two years before All the organs were found sound, but in using the stethoscope a drop of milk escaped from the nipple, and the patient casually remarked that she "still had milk " The menses were regular, and analysis of the milk showed that it was not due to a new pregnancy Antipyrin was administered to suppress the milk secretion, about 1 5 gm a day, fractioned By the end of a few days it was impossible to express any milk from the breasts, and without further medication the patient rapidly regained her usual health Beltz reported a similar case in the *Bull de la Soc Méd* of Rheims in 1876 In his patient the milk secretion persisted for more than four years, although milk escaped only under pressure, except during the menstrual period, when there was always an increase The patient complained of pains in the stomach and kidneys, debility and lassitude, and there was considerable anemia. Whenever a woman is anemic and debilitated without apparent cause after weaning a child the possibility of a latent lacteal secretion should be borne in mind

40 **The Spirit of Asepsis.**—The requirements of true asepsis in the treatment of wounds are plenty of good, soft, porous, absorbent gauze, thoroughly sterilized, and applied to the wound with a "muff" around it of absorbent cotton These supply the conditions for perfect physiologic repair and normal defense of the wound process Wet dressings, impermeable coverings, antiseptics, etc , are merely breeding places for germs or devitalize the tissues, enfeebling their resisting powers, while not materially enfeebling the germs In infected wounds it may be necessary to apply hydrogen dioxid or hot saline solution to the depths of the wound, but above them the dressing should be as above All moist, airtight methods of treating wounds should be totally abandoned

43 **Spinal Motor Localizations.**—Marinesco has been conducting research for years on the motor localizations in the spinal cord His work was done mostly on dogs, studying the reactions at a distance after section of nerve trunks or muscle nerves, or resection of muscles after severing the nerve roots He summarizes his conclusions in this article, which is accompanied by 23 illustrations He has found that the muscles which possess a common function are represented by groups of nerve cells arranged in relation to each other to correspond with the anatomic arrangement of their corresponding muscles By this combination Nature economizes material while ensuring rapid and useful functioning This explains the piling up of the cells in certain parts

50 **Festschrift of Leipsic Obstetric Society**—The Leipsic Gesellschaft f Geburtshilfe recently celebrated its twenty fifth anniversary with much ceremony, Paul Zweifel presiding A Festschrift was published in honor of the occasion, a bulky volume of 578 pages, containing 22 articles, and printed as Vol lxxii of the *Archiv f Gynäkologie*, Berlin

53 **Lymph System in Uterine Cancer**—This monograph by Kroemer is very extensive and copiously illustrated with 37 figures and 6 plates, and a bibliography of 251 references, carefully sifted He proclaims that investigation of the glands should be the first step in surgical intervention Three requirements are essential 1, Exploratory excision to determine the indications for operating, 2, that patients treated by radical operation in whom the glands are found microscopically degenerated should be classed apart from others, 3, the material coming to the dissecting table should be utilized for microscopic examination and comparison with the clinical records

55 **Remote Results of Instrumental Dilatation**—Buddeben's experience with instrumental dilatation to facilitate delivery has been very unfavorable In 5 out of the 6 cases there have been consecutive disturbing parametritic indurations and cicatrices, or recurring inflammation in the parts Four out of the total of 10 patients thus treated succumbed to pre existing complications

56 **Connection of Epidermis Cells with Each Other and with the Corium.**—Merk presents evidence to prove that the epidermis cells are connected with each other and with the corium merely by juxtaposition and a mucilaginous vehicle They can be dissolved apart the same as a flake of sputum from a china surface

59 **What Do We Learn from the History of Hydriatic Treatment of Syphilis?**—Sadger summarizes his conclusions in the statements that there are undoubtedly cases which have been cured by the combination of hydriatic procedures and careful dieting, but that years are required to accomplish this result It is still an open question whether it is possible for all cases The duration of treatment can be much shortened and its success, perhaps, first rendered possible by combining the hydriatic course with iodid or mercury and a careful diet This combination has a number of advantages over either alone The water treatment relieves intolerance to the drugs, and may possibly first render them effective The dosage may be reduced, as the hydriatic treatment enhances their efficacy and makes the skin more receptive The water course expels the mercury from the system as soon as it has accomplished its purpose and hardens the patient to climatic changes The general health also benefits materially, the various phases of the syphilis are shortened, and the subjective prodrome banished. The indurations are rapidly and permanently dispelled The special domain of hydriatic procedures in syphilis is in cases of severe mercurial intoxication

63 **Ichthyol Internally in Mycosis Fungoides.**—In a very severe typical case of mycosis fungoides, Hodara administered ichthyol internally—5 to 15 gm a day—for two years and then only during the summer for three more years Marked improvement was evident from the first, and the patient is now practically cured She was a woman of 60, who had suffered from the affection for six years previous to commencing taking the capsules of ichthyol Similar benefit was attained in another case, and a third patient was also practically cured, but arsenic was given at the same time in this case The diagnosis of mycosis fungoides was confirmed by the finding of a mononuclear leucocytosis The ichthyol promptly relieved the itching in every instance

71 Suprapubic Cystotomy for Prostatectomy J P zum Busch (London) —Die Entfernung der vergrösserten Prostata vom Blasenschnitt aus

66 **Behavior of Leucocytes in Infectious Diseases**—Arneth reiterates his previous announcements that the methods of research on the blood count at present in vogue are absolutely inadequate He has established that the neutrophile leucocytes, instead of belonging all to one class, must be further classified according as they possess one or more nuclei He has found that these subclasses predominate in a characteristic manner in various infectious diseases, as is shown by 276 tables which he has compiled, each representing the examination of 100 neutrophile leucocytes In a case of miliary tuberculosis he found that nearly all the neutrophiles belonged to the classes with one or two nuclei, and many of these nuclei showed morphologic changes During the entire course of the disease these findings were obtained every time, although the number of leucocytes was normal On the other hand, in a fatal case of traumatic tetanus the neutrophile findings corresponded to the normal average in every particular, even after treatment with Tizzoni's antitetanus serum In cases of varicella, measles mumps, erythema nodosum, etc, the findings showed that these infections are liable to cause severe injury of the neutrophile blood picture, although the total number of neutrophiles may correspond to the normal figure In classifying the neutrophiles he arranges his tables in 5 groups Group 1 (neutrophile leucocytes with one nucleus), with the subdivisions of, M (myelocytes), W (cells with nuclei only slightly hollowed out), and T (cells with nuclei much hollowed out) Group 2, neutrophiles with 2 nuclei, has three subdivisions, 2K (nucleus in 2 parts), and 2S (2 loop like parts), and 1K, 1S Group 3 has four subdivisions, Group 4 has five, as also Group 5 The average normal neutrophile findings determined by research on 15 healthy subjects is, in Group 1, M=0, W=.2, T=5 Group 2 is 2K=27, 2S=23 46, 1K, 1S=11 62 Group 3 has 3K=2 27, 3S=5 6, 2K, 1S=16 66 2S, 1K=16 4 Group 4 is, 4K=3 8, 4S=07, 3K, 1S=6 4, 3S, 1K=1 6, and 2K, 2S=4 73 Group 5 is, 5K=1, 4K, 1S=4, 3K, 2S=.4, 4K, 2S=07, and 3K, 3S=07 The average in round numbers is thus 5 per cent in Group 1, 35 per cent in Group 2, 41 per cent, in Group 3, 17 per cent in Group 4, and 2 per cent in Group 5 The article issues from von Leube's clinic at Würzburg It is supplementary to a monograph which Arneth has recently published in book form

72 **Appetite and Gastric Secretion** —Meisl remarks that the study of metabolism is incomplete unless we take the appetite into account at the same time It is a hitherto neglected but most important factor in the metabolism He regards it as an impulse from the cortex, inciting various reflex acts as it passes through the sensory centers, which are of the greatest importance for the utilization of the food It stimulates the secretion of saliva long before the influence of the ingredients of the food can be felt in this line, prolonging and enhancing the enjoyment of the food and getting the food into the best possible condition for its utilization in the stomach The appetite is the inciter of the "appetite gastric juice," without which the digestion of bread and albumin in the stomach is entirely impossible, and the digestion of milk and meat is a much slower and weaker process The appetite further increases the secretion in the pancreas and arrests the inhibitions which are liable to hinder the functioning of the pancreas And, finally, the appetite leaves behind it an agreeable mood, in which the cortex functionates more perfectly, and any inhibiting influences which may have previously existed are suspended The appetite is the highest phase of development of an instinct If we obey its mandates it not only affords us enjoyment, but it has a vivifying and stimulating action on the functions of all the organs, especially those of the cortex It is the highest mental evolution of the need of food, and is for the preservation of the individual what sexual love is for the preservation of the race

75 **Diagnosis of Arteriosclerosis of Central Nervous System** —Hnatek describes 2 cases In one, a patient with a suspicion of lues, but not the slightest indication that the brain was involved, was suddenly seized with headache, vomiting, vertigo and numerous subcutaneous hemorrhages Two weeks later there was also a weakness in the feet and in the bladder functions, followed in a month with nystagmus, partial oculomotor paralysis, dysphagia, anarthria, glossoplegia, anesthesia *of* tongue, right facial paralysis and spasmus nictitans There was no paralysis of the legs, but much weakness Death occurred in the course of ten weeks The patient was a woman of 38, with general lipomatosis, and the necropsy revealed *general arteriosclerosis*, most pronounced *in the vessels of the base of the brain*, with hypertrophy of left heart and dilatation of right ventricle Among the more striking *symptoms* was the high blood pressure, the difference in the pulse between symmetrically located arteries, which amounted at times to *ten beats*, and the so called stability of the pulse—*that is, the lack of* variation when the subject changed from the reclining to the upright position, or *vice versa* In the other case described the symptoms pointed to a tumor in the brain, with general arteriosclerosis, but the necropsy revealed extensive arteriosclerosis *of the vessels of the brain*, with consecutive, recent foci *of softening* in the white substance and in the gray nuclei with a *tendency to cyst formation*, malacia of the pons, hypertrophy *of the left heart and acute hemorrhagic nephritis* *The* patient *was a woman of 42* The incipient choked disc had been accepted as evidence of a tumor in the brain

76 **The Sewing-Machine and Health** —Nussbaum refers to statistics and his own experience to show that the position at the machine and the constant use of the legs are liable to cause congestion in the female genitalia and consequent inflammation The menses are frequently very irregular, and abortions, inflammation of the adnexa and other gynecologic troubles are unusually prevalent in this class of working women He advises that they should take especial pains to sit erect and breathe deep, frequently rising to change their occupation or to step out of doors or practice respiratory gymnastics Good ventilation and illumination *are particularly necessary for persons* who *have to use the sewing machine constantly*

77 **Failures in Treatment of Gonorrhea** —Finger mentions instances in which the gonococci had retreated to the prostate, where they remained, few in numbers and scarcely at all virulent, not causing the bearer the slightest trouble or even suggesting its possibility Marriage, however, was followed by infection of the wife The posterior urethra and the prostate are the usual sources of late trouble, and neglect of this possible localization may entail the severest consequences

78 **Treatment of Cholelithiasis with Chologen** —Winterberg's experiences with Glaser's chologen were eminently favorable He found it particularly effective in the cases of small calculi and also in certain gastric affections which simulated cholelithiasis, but vanished completely under the influence of chologen Its most important use, he thinks, is in prophylaxis, and he witnessed fine results in warding off cholelithiasis in the predisposed by its use

81 **Causes and Treatment of Gout** —Falkenstein attributes gout to malfunction of the glands in the stomach which produce HCl This results in defective digestion and defective metabolism in general, with the syndrome of gout as the final outcome The therapeutic indications are to supply the missing hydrochloric acid Treatment on this principle has been always well borne by his patients during the two and a quarter years since he made this discovery The treatment prevents the formation of new deposits, and in time—by the improvement in the general health—*it enables the organism to dis*pose of the old deposits *The subjects should not eat too much* or too frequently, but *otherwise may* eat ordinary diet, avoiding indigestible articles, fat food, cheese, eggs and the internal organs of animals on account of their large proportion of nuclein Sugar should also be strictly avoided Persons with a tendency to gout should avoid sugar in any form, either in ice cream, cake, candy or in any article of food With care in these respects, and constant taking of hydrochloric acid to supply the missing factor in digestion, the intervals between the attacks of gout become longer and longer, until finally the subjects find themselves entirely free and well

84 **Results of Immunization with Separate Elements of *Blood*** —*Among* the results reported we note that the tests dem*onstrated* the non identity of serum precipitin and erythro precipitin

85 ***Color Hearing*** —Chalupecky argues that the phenomenon of color hearing is merely a dual sensation, the result of exceptional *sensitiveness* on the part of the cortex—a *slight* exaggeration of the physiologic condition It is akin to the cold shiver that runs down the back in connection with certain sensations—another dual perception

86 ***Syphilis of* Nervous System** —Buraczynski's article is based on 20 cases The age of the patients was between 19 and *30 in 11*, between 30 and 40 in 7, and only 2 were over 40 *In* one case the infection seemed to have *originated* in the tonsil *In 18 cases* there were other manifestations of syphilis, but 4

were apparently exempt There were no neuropathic antecedents in any instance, and the heart and lungs were sound In 13 of the cases the nervous symptoms appeared within a year, in 4 they were not manifest until the third, fourth, sixth or tenth year Only 10 patients had received previous treatment, and it had been very inadequate in the majority His experience shows that continuous, energetic specific treatment will accomplish a complete cure in time in the majority of cases Some of the patients refused treatment, and he longs for obligatory measures for such cases One case of endarteritis terminated fatally, as no treatment had been attempted, the syphilitic nature of the affection not having been recognized In another case of ignored syphilis the first nervous symptoms were intense pains in the left foot The sciatic was found sensitive its entire length, knee jerk present, but weaker on the affected side The pains subsided under potassium iodid and vanished completely with inunctions Four similar cases have recently been published, the nocturnal type of the pains was an aid in diagnosing In another case facial paralysis was observed the second month after infection It developed slowly and was accompanied by headache, worse at night, all the symptoms vanished under inunctions The syphilitic nature of the paralysis in this, and a second similar case, was demonstrated by the presence of secondary symptoms and the lack of other causes, the youthful age of the patients and the brilliant results of specific medication

98 Modificazione morfologiche dei bacilli della tubercolosi in soggetti refrattari immunizzati e curati col siero specifico antitubercolare M Sciallero

91 **What the Maragliano School Has Accomplished.**—Professor Maragliano has commenced the publication, in a special *Annals*, of the work accomplished by him, or under his direction, in the line of the study of infectious diseases, tuberculosis in particular The points already established are enumerated—fourteen in all They all have been duly chronicled in The Journal (See page 961 of the last volume) The crowning demonstration is that of the possibility of curing tuberculosis in man by inducing a defensive process analogous to that which occurs in spontaneous recovery, also that the defensive materials (antitoxins and antibodies), administered by the alimentary canal, pass into the circulation and confer immunizing properties on the organism into which they have been introduced, rendering it refractory even to intravenous injection of virulent tubercle bacilli

93 **Formation of Specific Antibodies in Animals Treated with Aqueous Extract of Live Tubercle Bacilli.**—This research was undertaken to see if it were possible to produce specific antibodies powerful enough completely to prevent the development of experimental tuberculosis A large number of rabbits and guinea pigs were the subjects, and the results showed that an agglutinating power of 1/2,000 had been conferred on the serum, and that the antibodies were capable of preventing the development and reproduction of tubercle bacilli both *in vitro* and in other animals

94 **Improved Technic of Sero-Agglutination in Tuberculosis.**—Marzagalli rinses the tubercle bacilli in cold water until all the culture material is washed away They are then triturated with distilled water and the emulsion is filtered through a Chamberland, after which the fluid is ready for the sero agglutination test

95 **Study of Immunization to Tuberculosis**—Figari found that animals rendered passively immune to tuberculosis by serum from other animals treated with the aqueous extract of live bacilli were able to withstand otherwise fatal doses of human tuberculous material On the other hand, animals rendered actively immune for a time proved in the end less resistant He explains this contradiction by the fact that in passive immunization we introduce into the system defensive substances which, superposed on those already in the organism, confer sufficient immunity for purposes of resistance But when we induce active immunity the formation of defensive substances is stimulated to such an extent that the elements of the tissues producing these defensive substances become exhausted by the extreme task imposed on them and are rendered more susceptible than is the case when these elements are not stimulated to such an extent

97 **Morphologic Changes in Tubercle Bacilli.**—The conclusions of Goggia's research may be summarized in the statement that the predominance of aberrant and necrobiotic forms of tubercle bacilli in the sputa is an encouraging sign, as it indicates that the organism is working vigorously in its own defense

Riforma Medica, Palermo and Naples.

105 **Technic of Exploration and Operation on the Lungs.**—Cavazzani, in June, 1901, operated on a patient on account of an abscess of the lungs, and has since had occasion for intervention on a dozen more The results have been so gratifying that he recommends his technic for exploring the interior of the thorax without special apparatus and without fear of accidents It is based on the assumption that pneumothorax may be induced without fear of serious results, and the pleural cavity can then be sutured air tight, leaving two drains in it The air in the cavity is then aspirated through the drains and the openings closed air tight, or physiologic salt solution can be injected to displace the air and the openings be then closed air tight As the fluid is gradually absorbed the lung slowly expands to its

former volume By either means it is possible to explore and operate on the viscera inside the thorax without fear of complications from the pneumothorax He describes the details of his 13 cases In the first, he made a subperiosteal *resection of the* seventh rib, opening the pleura, incising the pleura and lung, evacuating an abscess the size of an orange, and tamponing The *cure was complete in three months* In his second case the abscess was small and at a depth of 7 cm from the surface He operated on the lungs of a child three times in one case, but the lesions were multiple and could not all be reached and the patient succumbed in time, as *in another case of lobular pneumonia* in a child In this case he mentions the return of resonance as the air in the thorax was aspirated and the *lung expanded after the operation* Case X was a woman of 27, presenting symptoms which had been variously treated as acute and chronic pneumonia Examination revealed a gangrenous abscess at the base of the upper lobe After resection of 9 cm of the *fifth rib the abscess was found at a depth of* 3 cm from the surface The cavity was the size of two fists It was tamponed and recovery was complete in three months The results of his operative intervention demonstrate that the thorax can be entered at any point in its periphery and can be explored without danger if the air that has entered is aspirated or displaced by a physiologic fluid He adds further that direct intervention on the lungs is feasible and practicable especially if the cavities left are filled with some harmless substance and the breach in the walls made as small as possible All his patients recovered except the 2 children

123 **Dissociated Respiration**—*Grocco studies the type of res*piration in which the physiologic co ordination between the movements of the diaphragm and those of the intercostal muscles is disturbed It is observed in endocranial affections and also in typhoid, pneumonia uremia, etc, that is it is liable to occur whenever the medulla is injured by the action of toxins congestions, asphyxia or infections He noticed it also in 2 cases of *neurotic respiratory spasm*

134 *Myringotomiya kak sredstvo ulutchshalushtchee slukh pri chron otitis media F T K Stephanovski (Concluded)
135 Contagiousness of Leprosy I I Hubert—O zarazitelnosti prokazi

126 **Unusual Forms of Anthrax in Man.**—Lintvareff reports 2 cases of anthrax of the lungs and digestive tract, mycosis pneumointestinalis, and 2 of malignant edema of the lids, with *one of malignant* edema with tetanus A differential sign of anthrax of the digestive tract or lungs is the observation of numerous small, circumscribed patches of cutaneous edema Anthrax bacilli can usually *be found in their* serous contents

128 ***Salicylates in Chorea Minor***—Four cases are related to illustrate the favorable effects liable to be attained by systematic salicylic medication

129 **Mosquitoes and Malaria**—Mosquitoes are numerous at the mouth *of the* Don river and malaria is prevalent but Zlatogoroff calls attention to the fact that the majority of cases occur during the spring months when the mosquitoes are comparatively rare At the *same* time, the transmission of the disease by the mosquitoes was beyond question, but some other factors may co operate in some cases

131 **Diphtheria of Puerperal Uterus.**—In the case described the patient had fever after instrumental delivery with decapitation of fetus at term Examination the sixth day showed a thick false membrane covering the mucosa of the uterus and plugging the os Diphtheria bacilli were found in it with pus cocci Serum treatment was instituted the ninth day and the patient was dismissed in good condition six days later

132 **Firearm Wounds of Stomach**—A young man fired a bullet from a revolver into his own chest It entered the sixth left interspace, but under expectant treatment was evacuated in the stools a few days later, and recovery was soon complete There had been only a little fever the first few days

133 **Microgastry**—Bendusky calls attention to the possibility of the stomach being congenitally very small and retaining its infantile type He thinks the condition is more liable to occur in women—*similarly to an infantile uterus*

134 **Myringotomy**—Stephanovski illustrates his technic and describes 16 cases in which he applied it to cure deafness resulting from chronic otitis media The deafness was completely cured in 12 5 per cent *and materially improved in 62 5* per cent, while the subjective sounds in the ears were partially or entirely banished in all No inconveniences of any kind were noticed after the paracentesis

ERGOT IN GENERAL PRACTICE*

ALFRED T LIVINGSTON, M D

JAMESTOWN, N Y

The chief object of this paper is to demonstrate that inefficient tone of unstriated muscular fiber is a common and serious element of disease, and that it is important to guard against, or to correct, such abnormal state of that tissue

The secondary object is to show that a drug which has been used therapeutically for three centuries for a single purpose, and for three decades for but one additional purpose, is the best medicinal agent at our command with which to tone the weak, relaxed, or paralyzed unstriped fiber, and, therefore, deserves, without exception, the first place, the place of honor and trust, in the physician's emergency case

The most common manifestation of atony of the unstriped fiber is an abnormal disturbance of the equable distribution of blood throughout the body The relation of the blood supply to the several organs or regions of the body varies normally (physiologically), dependent on their special functional activities at any given time, but such variations are included in what I term "the equable distribution of blood," and they do not imply any degree of atony of the muscular coat of any blood vessels

It is well recognized that a supreme activity in one region determines a more rapid or abundant flow of blood through that region and a lessened blood supply to other parts witness the mental apathy or somnolency accompanying the good digestion of a full meal

The abnormal (pathologic) disturbance of blood distribution is quite another thing, and depends on a relaxed state of the muscular coat of the blood vessels of some region or regions The location, degree and persistence of such vascular relaxation, alone or together with the influence of bacteria, autotoxins or other irritants, or of cold, heat, moisture, altitude, fatigue, traumatism or other etiologic factors, determine a great variety of diseases most of which would not occur if there were a good degree of tone in all vascular walls

A relaxed state of unstriped fiber elsewhere than in blood vessels and lymphatics as in the bowel and other hollow organs produces other disorders which indicate the same object in therapy, namely, a stimulating or toning of unstriped muscular fiber

A very small percentage of humanity is absolutely well which is practically equivalent to saying that as small a percentage has a good state of tone of all the unstriped fiber of the body, which is again equivalent to saying that disease in general depends on atonic unstriped fiber You are probably now thinking of bacteria, but of that bugbear later

One of the most common illustrations of abnormal blood distribution is "poor circulation," which is the passive form of too much blood in one region and too little elsewhere, and chiefly serious because it is a good soil on which to sow the seeds of disease The commonest active form is in "a cold," which ordinarily is evidenced in a simple catarrhal inflammation I am not aware that a bacillus has as yet been caught in the act of producing "a cold"

It will be more convenient to make some classification in treating this subject, and I will begin with disorders of blood vessels

DISORDERS OF BLOOD VESSELS

Inflammation of arteries, veins and lymphatics implies an abnormal disturbance of equable blood distribution, in that the minuter vessels of the inflamed or congested vascular walls are relaxed, dilated, and contain too much blood

Endarteritis—An interesting illustration in this department is a series of cases of endarteritis which I have encountered, involving a portion or portions of the abdominal aorta or its principal branches, the common iliacs, or their branches, the external iliacs The chief subjective symptoms were pain and shock the patient sometimes fainting, but more frequently only reaching the verge of that crisis Palpation disclosed one or more localized sensitive spots in the artery, and firm pressure usually produced pain in the back, opposite the inflamed spot In one instance a chronic, intense pain at the *vertex capitis*, which had begun after an extreme exertion, was markedly increased by pressure on the inflamed spot of the abdominal artery

Auscultation demonstrated a distinct friction sound at the spot or spots previously found to be sensitive to palpation, but not apparent elsewhere The paroxysms of shock, or shock and pain, followed exertion, such as lifting a heavy article, or sometimes the mere effort of rising from a prolonged recumbent posture Recovery occurred only in those cases that accepted the extreme course I prescribed, namely, long-continued absolute rest for from two to five months, and daily injections of ergot

The heart's pulsations were thus markedly slowed and softened, which gave longer intervals of rest from and less friction of the blood current over the inflamed surface I detail these cases because I have not found them clearly described in the books nor could I get light on them from prominent physicians who examined some of the cases

Septic Conditions—Septic inflammation of veins and lymphatics has repeatedly yielded to the ergot treatment This does not imply any antiseptic quality in that drug In some instances I also employed the constant current

---

*Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Practice of Medicine, and approved for publication by the Executive Committee Drs J M Anders Frank Jones and W S Thayer

Dilatation of Veins—In dilatation of veins it is desirable to secure some emptying of the greatly stretched vessels by gravity or pressure in order to allow the shortening by ergot of the overstretched and paralyzed unstriped fiber of their walls

I will refer here to edema because it is the direct sequence of circulatory stasis from vascular dilatation Ergot is striking in its relief of this condition, and the more so the more recent the occurrence of the edema

Inflammation begins in congestion, which consists of an area of abnormally dilated blood vessels If ergot is promptly and sufficiently administered, the congestion is relieved and the succeeding stages do not occur, in other words, the inflammation is aborted When it is not applied, or not sufficiently applied, in the stage of congestion, ergot will modify or limit the extent of the succeeding stages, and it is also an effective aid in promoting the absorption of exudates, because this process demands a restricted caliber of capillaries and lymphatics, which ergot tends to secure by contracting unstriped fiber

FEBRILE DISEASES

A very extensive class of diseases, in which an abnormal relaxation or paralysis of unstriped muscular fiber is the prime factor, is the febrile, whether from zymotic, infectious, autotoxemic or other irritants I say that the abnormal state of the unstriped fiber is the prime factor, because it is that state that determines, in some way, the serious and fatal elements of those diseases

I distinctly appreciate that the generally accepted theory to-day is that the prime factor in these diseases is the bacterium, waste product or other irritant, but the deduction which I am obliged to make from a rational consideration of my clinical experience is that if a good degree of that state which we denominate "tone" exists in this class of fiber to begin with or is promptly secured by proper treatment to that end, the effects which would otherwise result from those irritants do not occur, or, if they have had opportunity to initiate, those results will be dissipated or modified by a proper thorough and persistent treatment applied to the restoring of tone in that unstriped fiber which is deficient in tone The serious and fatal elements of febrile diseases may be summarized under the following heads

First Congestion and the succeeding stages of inflammation, including unresolved exudates

Second Hemorrhage from ulcerative corrosion of tissues, or from rupture of weak or greatly strained blood vessels

Third Disturbed function of glands or other vital organs, including disturbances of digestion, assimilation and elimination

Fourth Insufficient oxidation

Fifth The so-called vasomotor pareses

Sixth Exhaustion and paralysis of the heart

Congestion—Congestion and its sequences will be admitted to be related to vascular atony for, if the vessels are not abnormally weak, they will not be abnormally dilated, and if not abnormally dilated, there is no congestion

Hemorrhage—The hemorrhage from ulceration is plainly thus related, for ulceration succeeds inflammation and inflammation begins in congestion The weakness of vascular walls leading to rupture is due in part directly to a relaxed state of unstriped fiber, which permits overstretching from increased tension, and, in part, to trophic defects, which, in turn, are due to relaxation of the minuter vessels

Disturbance of Glandular Function—The dependence of altered or deficient function of glands or other organs and tissues, on atonic unstriped fiber may not so clearly appear, but I can reach no other conclusion after observing the restoring of function by various means that relieve internal congestions and stimulate unstriped muscular fiber

Assimilation and elimination require for their best performance a caliber of the minuter blood vessels that admits of sufficient lymph spaces in which the nutritive and waste materials may circulate

Insufficient Oxidation—Oxygenation is too little considered in relation to disease Oxygen is desirable as a stimulant to vital activities, and is necessary to the normal chemistry of waste, and, not only does vascular relaxation in the lungs interfere with the access of air to all the air cells, from which the oxygen is transferred to its carriers in the blood, but wherever there is congestion in the general vascular circuit there is interference with the proper transference of that element from its carriers to the tissues of that region, or to the waste elements that require oxidation

Vasomotor Pareses—As to the essential condition in the so-called vasomotor pareses, whether it lies wholly in the abnormal state of the unstriped fiber in the dilated blood vessels of the general circulation, or, in part, in an abnormal state of the vessels of the vasomotor centers, or partly in an exhausted state of the vasomotor centers, as vital batteries, I will not assume to say but this I will say, that stimulation, by the constant current of the vasomotor centers related to certain areas of the circulation, as of the brain, will correct the abnormal vascular areas so related, and that ergot which, I believe, acts directly on the abnormally relaxed unstriped fiber, accomplishes the same end, and that ergot is applicable to the abnormally relaxed fiber anywhere in the body, which is not practicable as to the constant current, and also that the usually employed medicinal agents, of which strychnin, digitalis and alcohol are the chief representatives, are unreliable and very often fail to accomplish the end desired Furthermore, that in serious states of cardiac exhaustion the usually employed stimulants are even detrimental and frequently directly determine death, because, while failing to correct the vascular defects which have produced the exhaustion and which, so long as they exist, will continue to oppose the heart, they add to its exhaustion by irritatingly prodding it to its utmost additional effort, which, continued, must lead to its utter failure

Exhaustion of the Heart—Exhaustion of the heart is generally treated as if it depended solely on waning force in the heart centers, which are, therefore, stimulated with all the armamentarium at command, which more frequently results in increasing its exhaustion than in diminishing it

The change effected by ergot in the action of the heart, as to a great variety of its abnormal manifestations including the very weak, and even absent pulse and the extremest tension, so great that the radial artery seemed ready to burst, has impressed me that the condition which produces cardiac exhaustion and paralysis is the abnormally relaxed state of some part or parts of the general vascular circuit, and that the indication is to correct that abnormal state rather than to depend solely on forcing the heart to greater effort by administering heart stimulants Very often such correction will be all that is necessary, but when that does not suffice, a judicious use of heart stimulants will be rational after such correction, when their use, before the vascular system is toned, would be as distinctly irrational

On the other hand, when the action of the heart is excessive and the vascular tension high, ergot will be calmative to the heart and diminish the vascular tension, by correcting the abnormal state of the circulation existing somewhere, that had been the irritating excitant of the heart, and I hold that this is more rational than the use of depressants for such purpose In such conditions of high vascular tension I have never found it necessary, after using ergot, to resort to depressant medication

From what I have said it will be recognized that I do not regard the raising of blood pressure as the *sine qua non* in states of low vascular tension, as in shock or collapse, but that the true *desideratum* in such states is to bring about an equable distribution of blood throughout the entire body by contracting all those vascular walls that are abnormally weak, relaxed and stretched, and this is the peculiar province of ergot

FUNCTIONAL NEUROSES

Another extensive class of diseases, in which the securing of an equable distribution of blood is the principal indication, is that denominated nervous, more particularly the functional neuroses

In a communication just received from Dr Adolph Rupp of New York, I am informed that Waring's Bibliotheca Therapeutica states that W Hamburger of Leipsic, in 1848, published a work on "The Extraordinary Curative Power of Ergot in Nervous Diseases" I am curious to see this work, published before I was born, and I will be greatly obliged to anyone who may put me in the way of obtaining it It apparently had as little influence on the profession at large as my own first published paper on ergot would have had but for the accidental presence at its reading of Dr Frederick Holme Wiggin of New York, to whose appreciative interest in the subject I am indebted for the wider interest the profession has since manifested

Beginning with the use of this drug in insanity, which I was taught by the late Dr John P Gray of Utica, I gradually extended its application by a process of analogic reasoning on similar pathologic elements (circulatory) in other diseases, until I finally grasped the general principle that in many nervous diseases there exists an abnormally relaxed state of some part of the vascular system, and that this is fundamentally causative of the symptoms commonly assumed to be related to abnormal states of the nervous tissues From this point of view many facts were rationally explained which I had not before clearly understood, and the more carefully I analyzed etiologic and pathologic factors and elements of these diseases the more assured I became of the correctness of this deduction

The principal symptoms that are associated with the so-called nervous diseases are pain, nervousness (including irritability, both mental and physical, and restlessness), spasm, convulsion, delirium, insanity, insomnia, stupor, or coma, disturbed function of sensory, motor, or vasomotor nerve tissue, and the various pareses

As generally applicable, the statement that "pain is the cry of nerve for food," is poetry of the Keats or Shelley type, highly imaginative The deduction I make from my own observation is that pain is usually a result of pressure, and that the causative pressure is usually from congested blood vessels The fact, however explained, is that most pain is relieved by administration of ergot Ergot contracts relaxed unstriped fiber, and the relaxed unstriped fiber of blood vessels is surely the most likely to be associated with pain.

Headache, as the most common form of pain, deserves especial mention as one of the kinds of pain which is almost uniformly relieved by ergot

The pain of pneumonia, of appendicitis, of neuritis, of inflammatory states in general, of some neuralgias, the all-over ache or indefinite discomfort of developing fevers, the agony of angina pectoris, and intestinal colic, are among the kinds of pain that ergot relieves, and, therefore, are doubtless due to relaxed unstriped fiber, chiefly in vascular walls

Nervousness, from its simplest type to the intense agitation of the reaction from alcoholic and drug addiction, is strikingly amenable to ergot, and indicates that motor as well as sensory functional disturbance is related to a disordered state of the unstriped fiber, and this is still more markedly demonstrated by the relief of spasm and convulsion by the same drug

Insomnia is generally conceded to be due to abnormal vascular states in the brain While I am writing, a subject is sleeping who fell asleep before I had completed the first injection of my solution of ergot (two fluid drams), which I administered within half an hour of his coming under my care That hypodermic injection was given at 10 p m, April 30, and it is now 4 p m, May 2 He has slept continuously during the forty-two hours, except when aroused to give him food or medicine The subject, a physician, has been a drug habitue for several years, and has latterly been using hypodermically a dram or two drams of morphia *per diem,* and, in addition, two drams or more of cocain each week. During the last day, April 30, he used two drams of morphia and a considerable quantity of cocain The sleep has been natural in appearance, and, though awakened with some difficulty, he was clear and calm when awake, and immediately fell asleep after taking what was given him The pulse has ranged from 64 to 80, and has been of good quality, and only a few times was a little spartein added to the ergot solution He has had no morphia nor other narcotic, nor any hypnotic[1] I do not class ergot as a hypnotic, but if you

---

[1] The case referred to is illustrative of the action of ergot in the general class of drug habit cases. At the end of sixty hours the crisis was passed and without a particle of suffering or delirium, or even of heart depression in spite of the immediate complete withdrawal of the extensive dosage of the drugs The sixth day he began to come to my office for treatment, static and constant currents and at the end of the second week he removed to the country where, at a farm house and living much out of doors eating and sleeping well he is gaining rapidly in flesh color and spirits He does not recall nor did he at any time manifest a desire for his drugs or substitutes.

Another habitué a woman is now under like treatment in the same public hospital and with the same satisfying results

Besides ergot the only treatment in either case has been cathartics laxatives and digestives dry cupping hot and cold sponging of spine and the constant or static current. The important work was accomplished by ergot

Abstract of record sheets of W C A. Hospital Jamestown, N Y

Case of H. L F admitted 9 30 p m April 30 1904

10 p m after tub bath was given 10 grains of blue mass followed by ergot solution, 2 drams (all ergot was given hypodermically)

May 1 1904 Slept soundly all night.

At 10 a. m. 2 5 and 8 p m ergot, 1 dram, the first three with sparteine, 1/10 or 1/20 grain Action of bowels secured with saline and enema. Liquid diet every three or four hours F E. Buckthorn 3 drams nocte. Pulse ranged from 64 to 80 temperature 6 p m. 99 8 F

May 2 4 30 a. m. "Sleeping soundly until now Wanted morphia this a m. 7 30 a m. Sleeping most of the time. 6 30 p m Very restless for two hours 8 p m Nauseated know of any other drug that will permit or procure such sleep in such a case, it is surely your duty to make it known to the profession

Promotion of sleep of a normal character, when ergot has been administered for some other purpose, has been noted hundreds of times in my experience, and this has been one of the most positive characteristics of the drug, from which I deduce that normal sleep is an accompaniment of a certain state of closure of the vessels of the brain, reducing the quantity of blood in that organ below that which is associated with the activities of the waking state

A recent case, illustrating the relation of ergot, and, therefore, of relaxed unstriped fiber to insomnia, delirium and pain, is worth relating

I was called to a neighboring city to see a man in whom these three symptoms had existed for six days His history evidenced that he had been nervously exhausted from overwork, and, while away from home on a business errand, he had an attack of influenza, the temperature reaching 103 F He apparently had some realization of the mental disturbance, as he had repeatedly said that if the pain continued much longer he would become insane Before I had finished giving him the first hypodermic of ergot he said the pressure in his head was relieved There was no delirium after the first hypodermic of ergot He slept, which he had not done from hypnotics and opiates The severe pain in head and back, which had not been relieved by the opiates, was promptly relieved by the ergot and soon dissipated His treatment, in addition to ergot, was one dry-cupping along the spine and clearance of the bowels by a mercurial and salines

SURGICAL CASES

I might enumerate other disorders or classes of disease to which relaxed unstriped muscular fiber is importantly related, but I will speak of but one more class in which it plays a serious and often fatal rôle, because the indication is not properly met. I refer to conditions requiring surgical operation, and I do so under the title of this paper because it is the general practitioner who should so thoroughly appreciate the indications and the means with which to meet them that, when the case is passed over to the surgeon, it is already prepared both for anesthesia and operation The surgeon's relation to a case is so often at the last moment that there is then no time for the preparation that I believe to be important, namely, the toning of whatever unstriped fiber may be lacking in normal tone

The important objects attained by this preparation of surgical cases are

First A more safe and comfortable anesthesia, avoiding nausea, retching, vomiting, mental excitement and excessive heart strain

Second Avoidance of shock from anesthesia or operation

Third Relief of shock from traumatism

Fourth Avoidance or modification of post-operative pain

Fifth In certain cases, avoiding intestinal paresis

Sixth In all cases, promotion of the process healing

In all these there is certainly a most urgent demand for a good state of tone in the unstriped fiber involved

The evidence afforded by the action of ergot in shock is that the condition is not so much a paralysis of vasomotor centers as it is a tremendous disturbance of the equilibrium of the circulation, the internal vessels being extremely engorged, rendering the efforts of the heart practically futile The indication is, therefore, primarily, to contract the dilated and engorged vessels which will send their excess of blood to the peripheral vessels, which again establishes an active circulation, the obstacle to the heart being thus removed It may then be found that the heart needs more stimulus than it can get from the exhausted nervous batteries, in which case the secondary indication appears, namely, for a judicious use of heart stimulants

I recognize that according to the prevailing theory today the prime indication is to raise blood pressure but I think that this theory will be found to be erroneous

Until an approximately equable circulation (equable distribution of blood) has been secured, the raising of blood pressure will generally be detrimental, even though it temporarily increases the force of the heart's action, and the subject will be all the more certain to die

METHODS OF TONING UNSTRIPED MUSCULAR FIBERS

From all that I have said it will be recognized that I regard the toning of relaxed unstriped muscular fiber as important in a great variety of diseases, and of vital import in many instances As to the means by which such toning may be accomplished, you have possibly guessed one that I have in mind, but there are others

Electricity—Electricity in general, but the constant current in particular, is of inestimable value to this end, and applicable in many more instances than is likely to appear at first thought to the occasional user of that force A truth which I clearly demonstrated in 1890, namely, that the constant current stores the individual with force, as it does the storage cell, is of much importance in this connection, namely that the constant current is essentially like the vital force in its effects on functional activities

Dry-Cupping—Dry-cupping aids materially in relieving internal states of congestion, directly, by withdrawing a considerable amount of blood (if several cups are applied) from the general circulation and indirectly by causing much damage to the superficial ves-

---

vomited" (This followed and I believe was due to cocoa with milk at 5 p m A T L) Ergot 1 dram at 4 30 and 8 a m 12 noon and 6 p m sparteine twice At 9 p m "applied 10 dry cups to spine" Ergot 2 drams with sparteine Buckthorn 2 drams nocte 10 p m "Sleeping quietly" Pulse, 68 to 80 temperature 99 4 to 100 2 F Bowels and kidneys sufficiently active

May 3 5 45 a. m "Slept well till 5 a m not as soundly as previously about 7 hours" 12 noon 'Pulse full, nauseated 4 30 p m' Rochelle salts ½ ounce "Vomited small amount 10 p m "Has been sleeping quietly" At 1 and 5 a m 12 noon 5 10 and 10 p m ergot 1 dram first time with sparteine At 2 15 p m 'Galvanism' (10 cells, one hour) Pulse 70 to 74 temperature 99 2 to 99 6 F

May 4 5 a m "Restless and nausea Slept most of night about 6 hours ' 'Pulse full and good all night ' 2 30 p m "Galvanism" 11 p m 'Very restless" Ergot, 1 dram at 5 a m ½ dram at 2 and 11 p m Lactopeptin with nourishment Pulse 76 temperature 98 4 F

May 5 5 a m Quite restless early in night did not sleep as well as usual about 5 hours' Ergot ¼ dram at 8 a m 7 and 11 p m 1 45 p m, "Galvanism" Pulse 76 78 temperature 98-99 8

May 6 2 a m Very nervous legs aching restless not sleeping well" 7 a m, "Had poor night Did not sleep well Aching and tired this a m 10 30 a m 'Static treatment at Dr Livingston's office Ergot ½ dram at 2 4 and 8 a m 10 minims at 1 10 p m 1½ drams at 5 and 9 p m (Diet enlarged A T L)

May 7 "Slept about 5 hours'

May 8 'Slept about 5 hours '

May 9 'Slept in all 7 hours

May 10 "Slept most all night' 8 a m Pulse 84 temperature 98 5 F respiration, 18

(In the remarks note was not made of the frequent naps during the day which in part accounts for the less sleep at night May 14 'Removed to boarding house on lake" A T L) sels, the repair of which detracts from the abnormal internal activities

Hot and Cold Applications—The alternate brief applications of hot and cold water, or hot water and ice, over the entire length of the spine unquestionably tones the nerve centers, either directly or by stimulating their vascular walls, in either case indirectly toning the unstriped muscular fiber which they supply with force

Massage—Massage, by its mechanical impulse to the venous circulation and by the increased assimilative and eliminative activities produced in the massaged tissues, aids in securing a more equable distribution of blood throughout the body

Mercurial Treatment—Mercury, by its so-called 'portal stimulation," but more particularly, I believe, by its notable stimulation of glandular activity, also greatly tends to a more equable distribution of the blood

Ergot—I might continue to enumerate measures, physiologic or therapeutic, of more or less value in securing the desired object, but they will occur to anyone who thoughtfully considers his teaching and experiences, and I will refer, in conclusion, only to that one other, which is the chief, the direct, the specific, and the only universal stimulant and tonic to the weak, relaxed, stretched or paralyzed unstriped muscular fiber, namely, ergot

Having employed this drug during more than thirty years of practice, and in a constantly widening sphere of application, and having observed in thousands of instances its exceptional therapeutic power, and in scores of instances a power that suggested magic, because of the immediate and wondrous change it wrought, I have come to regard it as the one drug without which I would feel impotent in the practice of my profession

This confident reliance has developed from the recognition that the efficiency shown in so many and so varied states of disease, was because of a really simple and single therapeutic action, and that the existence of a localized or more general state of abnormal relaxation of unstriped muscular fiber is always an indication for, and should determine a broad, rational application of this drug

I recognize that some of my statements are likely to be regarded as extreme, perhaps as unwarranted, because not in accordance with general experience, but I also recognize that the difficulty of acceptance is wholly due to the limitation of the general experience, and I do not hesitate to rest my reputation on this broad proposition, that the general practitioner, surgeon or specialist, who does himself and his patients the justice to apply in his practice, fully, judiciously and fearlessly, the principles which I have endeavored to clearly express, will demonstrate for himself that ergot is capable of accomplishing all I have claimed for it and more, and that, besides being the great equalizer of the circulation, relieving pain, procuring calm and comfort, and promoting sleep, aiding repair, increasing elimination, supporting the heart, releasing the habitué from his horrible thralldom, and accomplishing many other desirable ends, to some of which I have elsewhere referred, it is, to a degree that can not be asseverated of any other drug, the saver of life

THE SOLUTION AND METHOD OF ADMINISTRATION

By an unfortunate blunder, for which neither The Journal nor myself was responsible, there appeared in connection with my paper[2] on "Some New and Unusual Therapeutic Applications of Ergot," a formula for a solution of ergot which has given much unnecessary annoyance and suffering, and has unfairly prejudiced both patient and physician against the drug I therefore desire to dissipate such impressions which are unjust to the drug by giving two formulæ, either of which I can commend, and neither of which, if properly prepared and applied, will cause sufficient hurt or inflammation to constitute a serious objection to even the most nervous and sensitive patient, especially when the exceptional therapeutic benefit is taken into consideration The first, which I have used long enough to test its keeping quality, is solid extract of ergot, one dram, dissolved in sterile distilled water, one ounce Filter this solution and afterward add two minims of the purest chloroform and shake gently This solution sometimes stings a little while being injected, but otherwise is satisfactory

The second is solid extract of ergot, one dram, dissolved in a saturated solution (about two grains to the ounce) of chloretone in sterile distilled water, one ounce After filtering the solution, add two grains of chloretone and shake gently

The added chloretone is to secure an abundance of the preservative, and this is the most satisfactory preparation I have ever used, because, being somewhat anesthetic as well as antiseptic, it will not hurt, if injected slowly, as all hypodermics of ergot should be given This solution, however, is given tentatively, as I am not yet assured that it will be perfectly preserved for a considerable time It is satisfactory for short periods I take from five to ten and sometimes even fifteen minutes to apply a hypodermic of ergot It pays to take this time because of the better therapeutic effect, since, curiously, although so marvelously potent if not interfered with, ergot is distinctly less potent if interfered with by anything which increases vascular tension, as the strain of bearing a hurt, physical or mental activity, or erect posture In general, it is much better that the patient be recumbent while the ergot is administered, and that posture maintained for half an hour or so after the administration I recommend only the alcoholic (pharmacopeial) solid extract for solutions for hypodermic use, and I caution against the acetic acid solid extract for such purpose

Even in the alcoholic solid extract there is a slight acidity which it is desirable to neutralize in order to have the most perfect result as to absence of hurt and local irritation, and this is accomplished by adding three or four minims of a saturated solution of chemically pure bicarbonate of soda to the ergot solution just before administering it I commend this measure only to the physician who is willing to be at some pains to avoid even a little hurt and succeeding annoyance to his patient. Another matter of importance in making the solution is asepsis, as watery solutions of ergot are extremely prone to develop bacterial or fungus growth All utensils, bottles, corks, filtering paper, etc, used should, therefore, be sterilized, and the same care should be exercised as to the syringe and needles when administering The dose for an adult is from one-half to two drams of the above solutions, and the assertions of my various papers as to effects are based on such solutions made from the pharmacopeial solid extract prepared by a reliable house I have experimented with some solutions supposed to be about five times the strength of my solutions, which were evidently not so, and clinical results alone can satisfactorily determine such relative strengths Confusion and disappointment are likely to result from such disparities in solutions prepared for hypodermic use, and it would be more satisfactory if all manufacturers adopted the same strength of solution based on pharmacopeial solid extract. After thirty years of strikingly satisfactory experience with ergot, I am unwilling to accept statements of the futility of the drug in an indicated case unless I know that a proper solution has been properly applied in proper quantities to the case The syringe used for ergot administration should be all glass with asbestos packing, and should be of capacity of from one to two drams The ideal syringe has not yet been made

DISCUSSION

Dr R H Montgomery, Youngstown, Ohio—I am surprised at the apathy with which this paper is received I am sorry that it is buried under an avalanche of gallstones In our hospital the use of ergot has been attended with the happiest results when used according to the indications pointed out by Dr Livingston

Dr J O Stranahan, Rome, N Y—The use of ergot in the insane institutions of New York, as mentioned in the paper, was first suggested by Dr Gray of Utica, N Y His experience of three years in the Hudson River State Hospital in cases of paretic convulsions proved this agent to be of value He had at one time 100 paretics, and he universally used this agent in solution immediately on the onset of the paretic convulsions These patients recovered consciousness sooner by the use of ergot, and the effect was very lasting In private practice I have followed this principle, and I must say that in these cases of cerebral congestion, particularly meningitis, there has been no drug which has served me so well as ergot

Dr H Grad, New York—My observation with the therapeutic action of aseptic ergot has been entirely with surgical cases, particularly its action on nausea following anesthesia and the concomitant shock of the operation I know of no other therapeutic measure that will control and mitigate the feeling of nausea following anesthesia as a few judiciously applied hypodermics of ergot Nor is there any doubt in my mind that it has a decided beneficial effect on shock I know of no other drug that will bring that degree of calmness of nerve and repose of mind to the patient in his recovery from anesthesia as aseptic ergot Every prolonged anesthesia is followed by a degree of nausea, retching and vomiting which varies with each individual, but as a rule these symptoms are directly in proportion to the length of the time the anesthesia is administered and the quantity of anesthetic ingested Beside these symptoms, there are others which frequently arise, namely, headache, delirium and a feeling of wretchedness, indescribable but most distressing to the patient The popular saying, "I don't mind the operation, but dread the anesthesia," testifies to the fact that the suffering incident to the operation is not to be compared to the torture directly the result of a prolonged anesthesia Now, therefore, if we possess a therapeutic measure that will prevent, or even only mitigate, those disagreeable sequelæ of anesthesia it certainly deserves consideration In aseptic ergot we find such a measure, and those who will give it a trial will be charmed with its effect. Since I have been using aseptic ergot in these cases I have been able to give my patients a measure of relief for which they felt grateful, and I would be very unwilling indeed to part with so excellent a therapeutic measure

Dr James J Walsh, New York—My own experience with ergot is limited to seeing its effects on delirious alcoholics, where undoubtedly it is of great service Ergot is undoubtedly useful in those conditions in which we find a relaxation of the blood vessels in the abdominal region, here we may have an accumulation of much blood of the body, and it has been pointed out by German observers that practically two-thirds of the blood of the body may be contained within these abdominal vessels at one time Therefore, by toning up these blood vessels the circulation can be made better and certain symptoms may be made to disappear Dr Homer Wakefield of New York, who has seen good effects from ergot in many neurotic conditions, but who is unable to be present at this meeting, has asked that his opinion of the value of ergot in such affections be stated Dr Wakefield has found ergot of decided benefit in the treatment of heart disease with lost compensation, especially in combination with the Schott method of treatment Dr Wakefield has also found ergot of decided benefit in cases of dilated heart and the consequent lessening of resistance in the circulation, and this has been shown by the *x* rays to have become smaller in size

Dr Alexander Lambert, New York—In Bellevue Hospital in New York City it has been a part of my duty to attend to the alcoholics and morphin habitués coming in Last year there were about 8,000 alcoholics there, and they remained one, two, three, four, five or six weeks, or even longer In those cases it has always been difficult to lower the death rate beyond 3 per cent in nine years, those patients with wet brain rapidly sank, due to the exhaustion of delirium Since using ergot I have obtained a 44 per cent lower death rate. Ergot quiets the nerves Formerly I could tell by looking at the tongue of the patient how long the individual had been drunk when giving ergot I can not, ergot takes the shake out so quickly When I went on duty I found 16 cases tied in their beds, when I used ergot, within forty eight hours only one needed to be tied, the rest having a more comfortable time This agent certainly prevents the dilatation of the capillaries of the brain and contracts those already dilated, and ergot is the only drug in my experience of about ten years at Bellevue that would contract these and prevent or help cure the alcoholic wet brain The use of ergot in the treatment of morphin habitués takes away the craving for this drug and helps them through their period of misery and woe caused by the cutting off of morphin I have never seen a patient go into complete collapse when ergot was given I can speak most heartily of Dr Livingston's paper, and of the opinions he expressed regarding the use of ergot It is a drug that will be more appreciated in the future, and it is one of the few drugs against which my skepticism has been changed to unqualified respect

Dr. J B Taylor, Philadelphia—I should like to know why this drug should be given hypodermically rather than by the mouth. In country practice it is, in many instances, very difficult to give a hypodermic In giving it hypodermically, is there no danger of ergotism?

Dr Alexander Lambert, New York—I have given it every two hours for two weeks and never saw ergotism develop

Dr Alfred T Livingston—I prefer to use ergot hypodermically because then I am absolutely certain, from a given dosage, what effects I can obtain, by the mouth one can not be certain Again, ergot is often very offensive to the stomach Hypodermically, it is certain and inoffensive, by way of the mouth, it is an uncertain agent and may disturb the digestive tract. I have not employed it to any extent in rheumatism but it would seem to be indicated, because the fundamental factor in either inflammation or disordered function is an abnormal state of the circulation

---

Prophylaxis of Anthrax—J Lignières, director of the National Institute of Bacteriology at Buenos Ayres and later at Palermo, announces that it is possible to prevent infection from anthrax by proper disinfection of the hides of infected animals No disinfectants are known which will destroy anthrax spores without at the same time destroying the hides The anthrax bacteria, however, are extremely vulnerable It is possible to kill them all by immersing the hide for fifteen minutes in a 5 per cent solution of crude carbolic acid or cresil, creolin, etc If this is done at once after the animal is skinned no spores will develop and the hide is effectually sterilized His extensive tests have demonstrated that no spores develop in the hide until at least two hours after the animal has been skinned He advocates that every hide in an anthrax focus should be systematically disinfected in this way as a routine procedure, not restricting the disinfection to the known infected animals The hides are uninjured

XANTHOMA *

JOHN V SHOEMAKER, M D, LL.D
Professor of Skin and Venereal Diseases in the Medico-Chirurgical Hospital
PHILADELPHIA

History—A lad, 18 years of age, afflicted with peculiar, characteristic and unusual lesions on the hands, knees, posterior aspect of the thighs below the buttocks and on the eyelids, was brought by his father to the dermatologic clinic of the Medico Chirurgical Hospital, was shown to the class on several occasions and made the subject of a clinical lecture

Physical Examination—Small in stature, general lack of development Greatest weight, 79, present weight, 67 Thin, with almost no subcutaneous fat General appearance that of a boy of twelve Face marked with lines, giving the appearance of old age. Skin pale, showing a general anemic condition, complexion yellowish, subicteroid. Tongue flabby and pallid.

Chest narrow, scapulæ prominent, marked depression above and below clavicle.

Circulation poor, pulse weak Heart's action increased, apex beat displaced, diffuse, functional cardiac murmur

Liver enlarged, extending from fifth interspace to an inch below umbilicus

Spleen enlarged, could be easily palpated

Urine An analysis of the urine gave the following results Sp gr 1014, acid reaction, no albumin, no sugar, no sediment, hyaline cylindroids, blood cells, uric acid and urates in abundance

Blood—An examination of the blood by Dr L. Napoleon Boston revealed Red corpuscles, 3,990,000, white corpuscles, 20,000, hemoglobin, 60 to 67 per cent Dr Boston also contributes the following notes concerning the blood The red cells were pale. There was marked variation in the size of the red cells, many of them being greatly oversize, while others were scarcely one half the normal diameter The viscosity of the blood was diminished. The red cells stained feebly, as a rule, cells nearly colorless were often seen. The central pale spot in the red cells was much enlarged, and at times this pallor extended to near the margin of the cell The hemoglobin had been extracted from areas in the protoplasm, and these pale areas overlying such degeneration resembled somewhat the effect produced by the malarial parasite. No pigment was seen in the red cells The differential leucocyte count was as follows

	Per cent.
Polymorphonuclear cells	66.0
Large lymphocytes	4.5
Small lymphocytes	15.4
Eosinophiles	6.0
Myelocytes	3.0
Large mononuclear	4.5
Transitional cells	0.6
	100.0

Description of Lesions—The palmar and dorsal surfaces of both hands were covered with small growths, which had been in existence for about six months They first came on the hands The affected regions did not ache spontaneously, but were painful on pressure The boy could not grasp objects firmly by reason of the tenderness of the palms The earliest lesions occurred on the palms, especially in the flexures of the metacarpophalangeal and phalangeal joints They were symmetrically arranged, and a description of one hand will do for both An artist, with deliberate intent and skill, could not more accurately copy the picture from palm to palm The palmar aspect of the thumbs and fingers were *studded with* discrete tubercles, most prominent in the flexures of the joints At the base of the thumbs were numerous tubercles which presented a linear arrangement Lesions were similarly distributed, corresponding to the principal lines of the palms They were also perceptible between the fingers The disease was likewise conspicuous over the knuckles, although the lesions in these situations were less numerous and distinct than on the palms An equal symmetry was observed in the location of the growths on the backs of the hands Lesions were observed between the fingers, and in the *flexures of the elbows* they were confluent The distribution was symmetrical on both arms Large lesions were scattered, though more sparsely, over the back. Some of the largest tubercles, about the size of a pea, were situated below the gluteal fold. Lesions existed behind each ear and on the scalp The upper and lower lids of both eyes were covered with numerous small lesions They were present on the dorsal and plantar surfaces of both feet and between the toes Walking was impeded and kneeling was painful

In various situations the lesions were both nodular, or discrete, and *confluent Small nodules* were *seen on the penis* A patch existed on the mucous membrane of the mouth, corresponding to the attachment of the upper lip to the alveolar process There was a spot of the same kind on the lower lip and others at the angles of the mouth, and one on the uvula. *Several were situated within the nostril* Those *located on the* mucous membrane were rather more conspicuous than those on the skin, owing to the contrast between their yellow color and the red of the mucous membrane

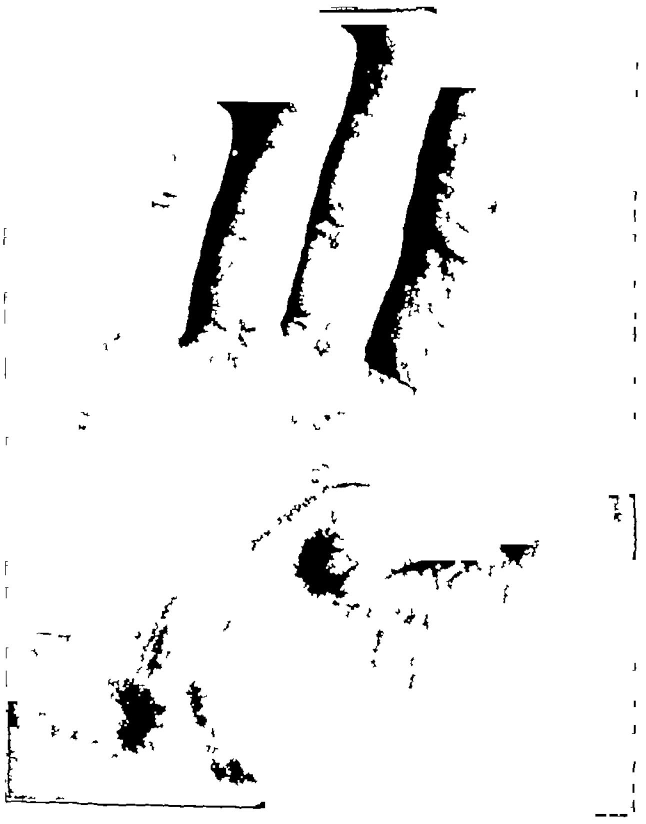

Fig 1—Palm of a typical case of xanthoma.

Many of the lesions were slightly elevated, others were plane with the surface They were of a yellowish color and resembled fragments of chamois leather embedded in or attached to the skin As the father expressed it, they are particularly numerous where the skin is 'slack," or where it is habitually brought in contact with objects

Diagnosis—Although this case represented a *rare affection* yet its features were so distinctive that there could be little difficulty in forming a diagnosis The yellowish color might possibly be suggestive of pus, but the *contents* of the tubercles were neither fluid nor fluctuating, the lesions were rather soft but nevertheless of firm consistency There was no resemblance to acne or any *other inflammatory* disease of the skin There was more analogy to milium, which is sometimes of a yellow color, appears principally on the upper eyelid and other parts of the *face*, and *may* remain stationary for years Mil ium, however, contains sebaceous matter, which may be forced out by pressure after the surface has been pricked. This was not possible with the tubercles of the case now reported.

---

* Read at the Fifty fifth Annual Session of the American Medical Association. In the Section on Cutaneous Medicine and Surgery and approved for publication by the Executive Committee Drs. H W Stelwagon J A. Fordyce and H G Anthony

CLASSIFICATION

The permanence of the lesions indicates that the disease should be classified among the new growths or tumors of the skin. The structure and the distinctive hue of the lesions are evidence that it could be no other than the affection which is named for its color—xanthoma, from ξανθός, yellow. Ordinarily, there is little scope for error, although multiple dermoid cysts have been mistaken for xanthoma, from which they could only be differentiated by microscopic examination. Urticaria pigmentosa, which occurs during infancy or early childhood, has sometimes been confused with xanthoma, a fact which is suggested by the very name which some writers have bestowed on that rare variety of nettlerash, viz., xanthelasmoidea. The possibility of error is all the more marked when we reflect that pigmented wheals may persist as permanent new formations of the skin and subcutaneous connective tissue, and that their color may be yellow. Wheals, however, are of firmer consistence than the tubercles of xanthoma. Itching is a much more prominent feature in urticaria than in xanthoma.

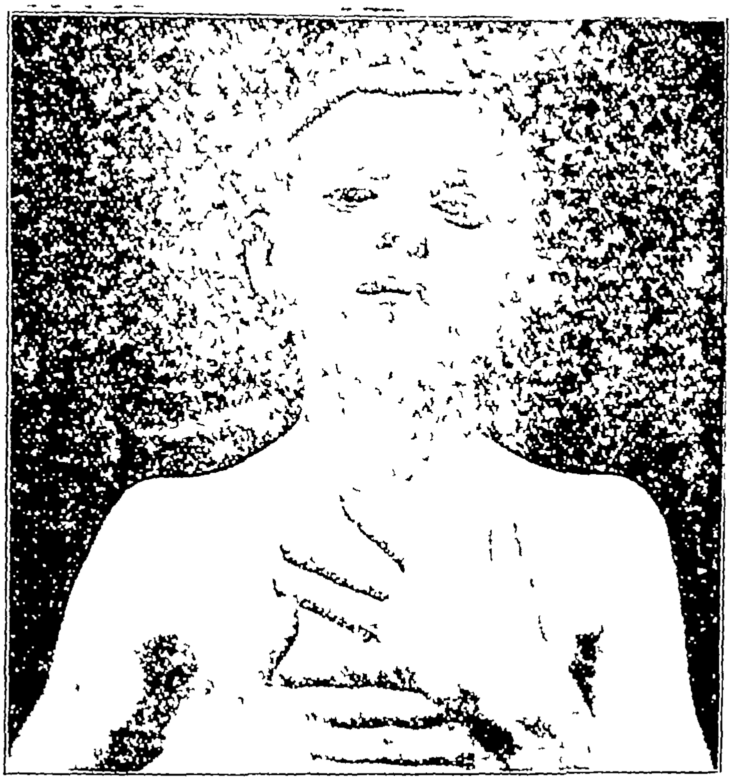

Fig. 2.—Lesions of xanthoma.

SYMPTOMS

Xanthoma is divided into two varieties, according as the lesions are plane or raised—xanthoma planum and xanthoma tuberosum. The spots of xanthoma planum are smooth, sometimes slightly elevated and of a yellowish hue, which has been aptly compared to that of chamois leather. On account of the buff or yellowish color, the disease has also been known as xanthelasma. The abnormal pigmentation has suggested another title for the malady, vitiligoidea. A multiplicity of names or titles for the same disease is undesirable, as it is liable to lead to confusion.

The lesions of xanthoma may be round or elongated. In the case now under consideration, many exhibited a linear arrangement. They may be as small as a pin's head or as large as a pea, and, indeed, in some instances have acquired much larger dimensions. Duhot has recorded a case in which some of the tumors were as large as a walnut. W. Moser encountered a case of a boy in whom multiple mushroom-like growths existed from the size of a pea to that of a hen's egg or larger; they were not tender or painful.

Xanthomatous skin does not seem to be thickened when pinched up between the fingers. After attaining a certain size the lesions generally cease to grow. The eyelid is a favorite location. Cases in which the disease is limited to the eyelid are much more common than those in which the lesions are more widely distributed, and which have been called xanthoma multiplex. In young persons most of these cases are congenital; in adults they are associated with jaundice or diabetes. The lesions have been seen on the cornea, in the mouth, esophagus, trachea, spleen, lining membrane of the bile ducts, liver, heart, aorta, and in the abdominal muscles. Tendons and serous membranes have also been implicated. Adjacent spots may coalesce. Xanthoma of the cornea is extremely rare. Gaucher and Herscher described a case[1] in which the cornea was involved, and stated that they had only been able to find one other case previously reported. The patient was three and one-half years of age, and was probably syphilitic. There was double interstitial keratitis. The keratitis was prior to the ocular xanthoma, the nutrition of the cornea had been reduced, and it had become a spot of least resistance. On the right cornea was a yellowish deposit of irregular shape and plane edges. There were characteristic tubercles of xanthoma on the cheeks. The nodules of xanthoma tuberosum are, as a rule, about the size and color of those of the plane variety, and round in shape, though they have been seen as large as a small apple. The large growths are due to an aggregation of tubercles, and are more irregular in form. In both varieties of xanthoma the color may vary from a light to a dark shade of yellow.

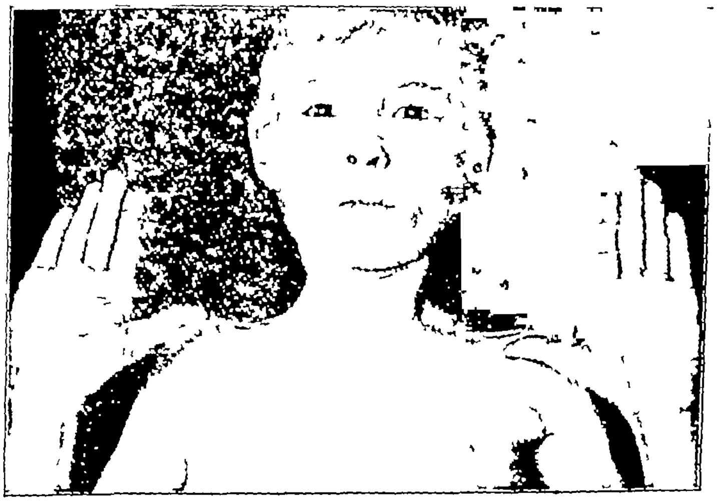

Fig. 3.—Typical lesions of xanthoma.

Xanthoma is more frequent in women than in men. The most usual site of commencement is on the inner canthus of the eyelid, and more particularly of the left eyelid. It begins as a macule. The coalescence of several patches sometimes forms a semicircle around one or both eyes. Subsequently other parts may be attacked. The disease is generally tardy in its progress. Large growths overhanging the eye have been known to interfere with vision. Korach and Hertzka have reported cases in which the evolution occurred within a few weeks, involving the greater part of the body, accompanied by icterus and pruritus. Dr. George T. Jackson of New York observed a case in a boy of 5 which began when the patient was 3 months of age, and attacked all parts of the body except the hands, feet and scalp. Prof. McCall Anderson witnessed an apparently congenital case in a child 3 years of age. Xanthoma, especially of the tuberous variety, is rare in children. Richter had as a patient a 9-month old girl afflicted with generalized xanthoma, marked especially by tumors. The mother thought that the disease had followed the bites of insects when the babe was 3 months of age.[2] Most cases occurring in early life are hereditary or congenital.

---

[1] Journal des Maladies Cutanées et Syphilitiques, 1900, p. 48.

Some cases of xanthoma have been described which seemed to be of hereditary origin. Torok knew of a family in which it had affected three generations. Hilton Fagge mentions a mother and daughter who had xanthoma, and in whose family it had occurred for four generations. Hutchinson reports a case of xanthoma in two brothers and a paternal grandmother. Crocker had a case in a stout, country lad of 18, in which the lesions were symmetrically situated on the elbows and knees, an elder brother had the same disease on the elbows. Xanthoma is rather commonly associated with disease of the liver and jaundice. It has been known to develop during the course of diabetes or gout. Jonathan Hutchinson has described an interesting case. The patient had inherited gout, of which he had had several attacks, and of which physical evidence existed in enlarged bursæ and fusiform swellings in connection with numerous tendons. In consequence of a severe fright, jaundice supervened, after which xanthoma appeared on the eyelids. The patches were symmetrically arranged. Subsequently small streaks of the same disease appeared over the right olecranon process. The patient's father and maternal grandmother had had xanthoma of the eyelids. Under the title of xanthomatosis the case has been described of a woman, 35 years of age, who had slight mitral insufficiency, stationary for several years, rheumatism, hepatic colic with or without jaundice, but no gallstones. This patient had xanthoma planum of the eyelids and a small fibro-fatty tumor of the abdominal wall.

In the opinion of Besnier, xanthoma of diabetic origin manifests a tendency to spare the eyelids and locate itself in the mouth. This writer furthermore states that buccal xanthoma progresses rapidly, but may spontaneously disappear. Diabetic xanthoma runs a more rapid course than when the disease is due to other causes. A few cases are on record in which xanthoma preceded the glycosuria. Another case is mentioned in which sugar had entirely disappeared from the urine fifteen months before an eruption of xanthoma occurred. Sequiera had a case of diabetic type without glycosuria. The patient was a man, 45 years of age, in whom the disease had existed for six months without any impairment of the general health. He had never had jaundice, but there was slight enlargement of the liver. According to Malcolm Morris, jaundice never accompanies the xanthoma of diabetics. Up to the year 1900 but 30 cases of diabetic xanthoma had been reported. Several have been published since that date. An interesting case was studied by Sherwell and Johnston.[3] The patient was a diabetic woman, 40 years of age, who had xanthoma on the arms, elbows, knees and buttocks. In fact no part of the body was totally exempt. It was present also on the palms, soles and scalp. The eyelids, an ordinary site, were spared. The lesions were painful when touched. It was difficult to handle objects, walk or lie down in bed. She had a sensation as if foreign bodies, such as peas or balls, were embedded in the skin. Antidiabetic diet had a remarkable influence on the eruption, which rapidly disappeared. Coincidently she lost the feeling of foreign bodies in the skin. In the course of two or three weeks she was able to use her hands, walk and lie on her back. When the patient first came under their observation, the eruption, when seen from the other side of the room, looked very much like confluent smallpox in the suppurative stage. Dr. Abraham has had a case of xanthoma in a diabetic woman, 32 years of age. The eruption had been in existence for four months. She was subject to biliousness. The lesions were painful when pressed. Women are much less liable to diabetic xanthoma than men.

Xanthoma diabeticorum, or the diabetic type as it is also called, differs in some particulars from the other varieties of the disease. The onset is more rapid in diabetic cases and the eruption may speedily vanish, as in Sherwell and Johnston's case. The lesions are of somewhat different aspect. They present some signs of inflammation, and consist of yellowish points on hyperemic bases.

The lesions of xanthoma usually remain for a long period or during life. In a few instances they have spontaneously disappeared without leaving pigmentation or cicatrices.

In cases of xanthoma multiplex the lesions are generally both plane and nodular. The spots are more common on the eyelids and flexures, the tubercles most frequently occur on the knuckles, elbows, knees and buttocks. The disease is commoner on the limbs than on the trunk. Lesions on the knees may be the source of discomfort or pain.

PSEUDOXANTHOMA ELASTICUM

Under this title Balzer described a form of eruption which bears some resemblance to that of xanthoma, being of a yellow color. Microscopically, however, it seems to be due to fatty degeneration of elastic tissue. A second case has been reported by Chauffard, and a third by E. Bodin. In these three cases the lesions were found on the front of the abdomen, base of the neck, axilla and groin, the knees, elbows and eyelids were free from disease. The evolution was slow, there was neither jaundice nor liver trouble, but there was tuberculosis in every case. The lesions were small masses of granular substance constituted by swollen and segmented elastic fibers, etc. Bodin regards this species as only provisionally attached to true xanthoma.[4]

PATHOLOGY

Xanthoma is a connective-tissue new growth undergoing fatty transformation. The lesion consists of irregular, uncircumscribed aggregations of large cells which have a clearly defined outline and possibly a cell wall with small nuclei, sometimes several in a cell, and with cytoplasma, characterized by closely massed fat globules. The cells occupy the spaces between the bundles of connective-tissue fibers belonging to the reticular layer of the corium, sometimes extending to the papillary layer. The epidermis shows slight atrophic changes. According to Touton, the fat is deposited in proliferated connective-tissue elements. In sections made by Prof.

[2] Journal des Maladies Cutanées et Syphilitiques, 1903, p. 531.

[3] Journal of Cutaneous and Genito-Urinary Diseases, Sept., 1900.

[4] Journal des Maladies Cutanées et Syphilitiques, 1901, p. 122.

Joseph McFarland, there were scarcely any evidences of inflammation exhibited Some writers, as Crocker, Chambard and others, believe that the disease originates in a chronic inflammation with proliferation of round cells As these are not invariably present, however, Touton and others refuse to accept the inflammatory theory All authorities agree that it is the fat in the cells that gives them their yellow color

Pollitzer, following Unna, teaches that xanthoma of the eyelids is due to degeneration of muscular fiber embryonically displaced, and that it differs from xanthoma tuberosum and xanthoma diabeticorum in this respect Clinically, I should regard the different forms of the disease as the result of a process identical in its nature, though differing in some histologic details perhaps, for, as in the case which I now report, we see plane and nodular lesions on the same person Not infrequently the disease begins on the eyelids and spreads to other parts of the body

ETIOLOGY

In reviewing the course and associations of the disease, I have anticipated some of the chief points of etiology I have spoken of the close connection which often exists between xanthoma and disease of the liver, gout and diabetes, and that it may be of congenital or hereditary origin Xanthoma palpebrarum is more common in women than in men, contrary to what occurs in xanthoma of diabetics It generally begins in middle life and is most frequent in people of dark complexion

TREATMENT

When xanthoma is confined to the eyelids, or when the tubercles are not numerous, they may be removed by excision Great care must be taken in order to avoid the occurrence of ectropion or epiphora Cauterizing and curettage have sometimes succeeded Kaposi used soft soap Morrow, in a case of nodules on the soles and knees, effected an improvement by means of a 25 per cent salicylic acid plaster Dr James C Maguire made use of monochloracetic acid, applying it to a small spot at a time and gradually going over the entire diseased area A 5 to 10 per cent solution of mercuric chlorid in collodion has been recommended Electrolysis has been used by Hardaway, Wende, Pansier and Leviseur Dr Willmott Evans treated a case by means of the *x*-ray The disease affected both elbows and was of seven years' duration He subjected one elbow to ten exposures of fifteen minutes each with a very satisfactory result, the elbow becoming practically clear

Wilson and Besnier advised constitutional treatment The former gave nitrohydrochloric acid, with an occasional blue pill, followed by arsenic Besnier administered phosphorus first, succeeded by arsenic, and reported a rapid removal of the growths by this method

The diet and other measures which are of service in diabetes have exerted an excellent influence on xanthoma, due to that disease Arsenic has also been given with asserted benefit

TREATMENT AND PROGRESS OF THE PRESENT CASE

The patient was first seen on Oct 16, 1903 On account of his unsatisfactory general condition he was then ordered

R	Ferri lactatis	gr 1/4	016
	Strychninæ sulphatis	gr 1/100	00065
	Acidi arsenosi	gr 1/100	00065
	Salicini	gr ii	12

M Ft pil No i Sig One such pill to be taken three times a day

No local application was given, as the disease was so widely spread On November 6 the boy's subjective condition was somewhat improved On November 13 he reported that he felt better, and it was thought that he was a shade less pale He was kept under observation, and on Jan 22, 1904, was again brought before the class At that date it was evident that he was losing ground The anemia had increased On March 23 he was thinner—a mere skeleton—and was having night sweats An examination of the chest gave a negative result

On April 23 the patient's abdomen was distended and very hard on the right side He was very weak, had lost appetite, had abdominal pain, and sometimes vomiting He was placed on

℞	Acidi nitrohydrochlorici dil	m x	60
	Tinct gentianæ co	ʒi	3 75

M Sig One such dose to be taken after each meal

He was also ordered

℞	Pil strychninæ sulphatis	1/60	0011

M Sig For one dose (before meals)

Xanthomatous deposit was probably taking place in the liver

The boy had been watched most carefully by the clinical assistants His father brought him to the dispensary at stated intervals With the exception of some slight improvement at first, his condition gradually grew worse At about the time of the last note one of the assistants visited the patient at his home—he lived in a distant part of the city—and found him in a feverish state, very much prostrated

REMARKS

This is a very interesting case, an excellent example of xanthoma multiplex The exquisite symmetry with which the lesions were arranged, more particularly on the hands and arms, claimed attention, and is quite characteristic of the variety of the disease by which we were confronted It was a case of xanthoma multiplex exhibiting patches, tubercles and nodules, both discrete and confluent Although the eyelids are the commonest site of the eruption, and although they were typically involved in this case, yet it was not in this situation that the disease first made itself manifest

The morbid process began at an early age in this patient With the exception of the few congenital or hereditary cases, xanthoma develops, in most instances after the age of 40 The lad was naturally of light complexion, which is also against the rule The rather plentiful deposit of xanthomatous material on the mucous membrane is among the less usual manifestations Although I have observed a number of cases of the disease, yet this was the first occasion in which I had seen it attack the mucous membrane

The poor physical development of the lad and his unpromising systemic condition are to be specially noted As a general rule, the prognosis of xanthoma is good as to life The genesis of his case seems to depend on the renal involvement with an inactivity of the liver and anemia, as evidenced by the examination of the urine and blood The stunted growth would seem to be only an interesting coincidence

The evolution was rather rapid considering the large amount of surface covered In this respect it somewhat approximates the cases observed by Korach and Hertzka Its progress was accompanied by much itching This symptom is more particularly distinctive of diabetic xanthoma, but no sugar was found in the patient's urine

The pain elicited by contact with the lesions was a marked feature of the case

Cases exhibiting multiple lesions are rare The striæ so well marked on the hands are not unusual in cases affecting the palm The case recorded by Duhot also illustrated this arrangement In Duhot's case the generalization was very complete, but, unlike that which I here report, the face, neck and genital organs were spared

The lesions consisted of tubercles and tumors, they were yellow and firm The palms and phalanges were striated Some tumors had spontaneously and entirely receded In Duhot's case there was no diabetes, but hepatic antecedents were noted

The coalescence of adjacent lesions was particularly observable in the case of my patient

DISCUSSION

Dr. A W Brayton, Indianapolis—Dr Shoemaker has emphasized the extreme rarity of these generalized cases of xanthoma which justifies him in calling attention to them I saw a case in Indianapolis several years ago, in a woman of 39 I think one fourth of her body was covered to the same extent and with as great a variety of lesions as in this case I reported that case briefly in the *Indiana Medical Journal*, April, 1900 It is the second case I have had knowledge of in which the lesions were so extensive The urine was examined in that case with negative results The patient has passed from my observation, but I think that if she is still living she cannot recover The lesions had been developing for three years, surrounding the eyes involving most of the face, the knees and elbows, and particularly massive on the hands and arms and below the knees On the shins the tumors were from the size of a wheat grain to a lima bean On the palms the growths appeared as if strips of chamois skin were set in the "lines of life" The whites of the eyes were yellow, the urine was yellow, but gave no signs of bile pigments The liver appeared normal There was pruritus Crocker states that four fifths of the generalized cases have been associated with jaundice The disease is rare Ten years ago less than twenty cases of the diffuse form were known

Dr. William Allen Pusey, Chicago—A very exaggerated xanthoma was shown some time ago before the Chicago Dermatological Society and which has recently been under my observation The interesting point was that the patient a boy about 16 years of age, was suffering from polyuria without sugar The lesions were of the type of the ordinary xanthoma and did not present the picture of diabetic xanthoma So far as I know no other case of xanthoma associated with diabetes insipidus has been recorded

Dr. David Lieberthal, Chicago—Cases with such extensive distribution are not frequent. I wish to call attention to the fact that in this case, which is naturally one of infantile xanthoma, the eyelids are affected In 1882 a report was made before the London Pathological Society by Startin and Mackenzie, of the published cases of infantile xanthoma, eight in all, and in none were the eyelids found to be the seat of lesions About ten months ago, through the courtesy of Dr L Greensfelder, I had the opportunity to demonstrate a case of infantile xanthoma before the Chicago Dermatological Society This was not the case mentioned by Dr Pusey It was a boy of 10 years, physically well developed, but morally defective, a kleptomaniac The lesions were extensive not only in the skin and subcutaneous layer, but tumors were also found on the tendons of Achilles Dr Greensfelder operated on the case to ascertain to what extent the tendons were affected, and it was found that their sheaths were free, but that the tendons themselves were diffusely infiltrated by the xanthomatous process How shall we explain the development of fat in various localities normally free from it? There seems no doubt that there is an underlying, a severe, and probably an internal cause, especially when we consider Dr Shoemaker's case which shows a veritable cachexia I would like to ask Dr Shoemaker if lesions were found in the internal organs inasmuch as there was not only extensive affection of the skin, but also lesions of the mucous membrane of the mouth and throat.

Dr. Edmund L. Cocks, New York City—In the Skin and Cancer Hospital of New York there was a case in a young woman similar to this boy's case, only the nodules of the lips and nose were larger That case was gone over very carefully, but we could not find anything wrong except the condition of the skin Dr Bulkley used the x rays and the nodules diminished almost one-third, although the striæ have not diminished to any great extent I feel sure from the reports I have had of her case that she will recover

Dr Jay F Schamberg, Philadelphia—Dr Shoemaker's patient appears to have on the cutaneous surface every gradation of the xanthomatous process On the eyelids are typical lesions of common xanthoma planum, on the extremities are seen characteristic lesions of xanthoma tuberosum, and on the back is an inflammatory nodule closely resembling those seen in diabetic xanthoma The extent of the eruption and the pronounced effect on the boy's general health would suggest that he is suffering from a general disease of which the cutaneous lesions are merely conspicuous external manifestations, indeed, the clinical picture is quite analogous to a malignant internal neoplasm with multiple cutaneous metastases What has the physical examination of the abdominal viscera disclosed, particularly in reference to involvement of the liver and spleen? It is the careful study of severe cases of this character that will doubtless throw light on the lesions of xanthoma that are so commonly seen in persons enjoying apparent health

Dr. Edmund L Cocks, New York City—I have carefully examined the internal viscera and find the liver is very much enlarged, in fact, we have liver dullness extending below the umbilicus up to and even beyond the fifth interspace The spleen is also enlarged I think Dr Shoemaker mentions the examination of the blood, which shows marked anemia

Dr. D W Montgomery, San Francisco—The boy's protuberant abdomen would signify that some of the abdominal viscera are affected

Dr M L. Heidingsfeld, Cincinnati—I wish to record a case which I saw in November, 1902, in Evansville, Ind, in consultation with Dr Sidney Eichel of that city The individual was a cachectic white boy, aged 16 years, weight 68 pounds, height 4 feet 6 inches Three years previously a ruptured compensation from a mitral insufficiency resulted in general edema, which was relieved by treatment, and jaundice and enlarged liver, which have continued to persist. The liver at the time of consultation extended below the umbilicus and almost completely filled the right half of the abdomen The xanthomatous eruption began, shortly after compensation was ruptured, over the extensor aspects of the extremities, and was very generally distributed over the entire body in tuberous form, except around the knees and elbows where the lesions were very closely aggregated together and took on the form of xanthoma planum Urine until lately contained albumin, but at the time of examination was normal, excepting that it was reduced in amount, its specific gravity was 1 015 His sleep until lately was disturbed by frequent micturition Appetite remained good, bowels regular, general distress slight All organs except liver and heart apparently normal

Dr L Duncan Bulkley, New York City—When did the first signs of this disease appear?

Dr. Shoemaker—I do not think he gives a clear history Frank, how long have you had this?

The Patient—About ten months

Dr William L Baum, Chicago—In hearing the result of the blood examination I think it would be well if some examination of the pancreas were made in this case especially as to his digestion of fats In view of the fact that in some cases of polyuria there is a relationship with xanthoma would point to investigation along the avenues of the pancreatic cells which might show some relationship with the central nervous system This looks to me more like a secondary toxemic effect and it would be interesting to know what Dr Shoemaker's record of the case might be at some future time

Dr. Henry G Anthony, Chicago—This case, although presenting unusual features is not difficult to diagnose The cases which present the greatest difficulty in diagnosis are those in which there is no elevation the lesions consisting simply of yellow spots in the skin This variety is recognized as a separate form by the *Pratique Dermatologique* Dr Pusey showed a case of this character before the Chicago

Dermatological Society, the spots had been present on the forehead seven years We had a discussion in regard to the diagnosis I thought it was xanthoma, others thought it verruca planum

UNCINARIASIS IN THE SOUTH, WITH SPECIAL REFERENCE TO MODE OF INFECTION *

CLAUDE A SMITH, M D
Pathologist to Grady Hospital, Demonstrator of Pathology and Bacteriology, Atlanta College of Physicians and Surgeons, Professor of Pathology and Bacteriology Southern Dental College, Pathologist to Georgia Pasteur Institute Secretary Anatomical Board of Georgia
ATLANTA, GA.

In this paper I shall attempt to present some additional light on the mode of infection in uncinariasis or hookworm disease The views as presented before this Section a year ago[1] have been confirmed, not only by my own observations, but also by those of physicians in different sections, who, after reading the article in THE JOURNAL, have written to me regarding the disease as it exists in their sections

DISTRIBUTION AND PREVALENCE OF THE DISEASE

It has been my fortune to see cases of the disease from all of the coast states in the south, from Virginia to Texas, inclusive, with the exception of Mississippi but reports received from that state show that it is prevalent there as well While my observations have necessarily been confined principally to my own state, yet the evidence indicates that the disease is equally as prevalent in all our southern states I do not believe that there is any section of any extent in these states that is free from it It seems as if the entire country was literally saturated with it It is found on the highlands as well as the lowlands, and on the mountains as well as on the seaboard

RELATION BETWEEN UNCINARIASIS AND GROUND ITCH

I have previously called attention to the close relationship which I observed to exist between uncinariasis and ground itch, presenting clinical evidence that uncinariasis is always present in all cases which have had ground itch within eight years, that uncinariasis is rarely, if ever, present in those who have not had ground itch within that time, that of members of the same family, living under exactly the same conditions, those who have had ground itch within this time also have the uncinariasis, and vice versa, also that the severity of the disease and the number of parasites are almost invariably in direct proportion to the number of attacks of ground itch

While the principal object of this paper is to report some experiments of placing the larvæ on the skin to artificially produce the disease, I wish first to make a few general remarks regarding the symptoms and diagnosis of uncinariasis

SYMPTOMS

No one set of symptoms can be put down as diagnostic of uncinariasis, as they vary with the amount of infection and with different individuals For convenience, I have classified the disease under three types

First Mild cases, which have had only one or two attacks of ground itch, and therefore have only a small number of the parasites of the intestines, not sufficient to produce any diminution in the corpuscles and hemoglobin

Second The medium type of cases, which have usually had two or more attacks of ground itch, and have a much larger number of the parasites in the intestines, sufficient to produce a reduction of the corpuscles and of the hemoglobin, but which is not perceptible on inspection of the patient, but is readily shown by the blood examination

Third The severe type of the disease, those cases about which so much has been said in the past, and which have had numerous attacks of ground itch, and which usually have several hundreds of the parasites in the intestines and present all the symptoms of extreme anemia, which is readily recognized without the blood examination, and which is oftentimes so great as to interfere with the development of the individual

We can not draw a sharp line separating these three types, but I make this classification for the sake of convenience in considering the prevalence of the disease, and also to draw attention to the fact that those cases which can be suspected from the symptoms of profound anemia are not so numerous as the other two types combined

In cases of the first or mild type, there are practically no symptoms by which the disease can be suspected There is no interference with the appetite and digestion which might not be attributed to other causes, no reduction in the hemoglobin, and the patient feels strong and vigorous, as the body is able to nourish a few of the parasites without taxing its reserve power

In cases of the second type, there may be various symptoms of interference with digestion, and while the patient usually says that he feels fairly well and superficial inspection may not show any decided anemia, yet the blood examination will show the reduction in the constituents of the blood

In the third or severe type, the patient presents all the appearances of profound anemia The skin has a yellow parchment appearance, mucous membranes are blanched, the sclera shows clear white through the conjunctiva in which no blood vessels can be made out The face is bloated and expressionless and the skin over the exposed parts often appears to be much thickened and feels dry and rough The patient may be greatly emaciated, but this may be hidden by edema The patient is very weak, and if he attempts violent exercise quickly becomes exhausted and short of breath There is a decided systolic murmur, and the blood examination shows a decrease of from 50 per cent to 90 per cent in hemoglobin, and the red corpuscles may be as low as 1,000 000, or even less The appetite is capricious, perverted, and there may be nausea and headache The perversion of the appetite may be shown in a fondness for meal, clay, sand or other substances

Many physicians have written to me regarding the habit of dirt eating as being the mode of infection of the disease When I first discovered the disease in my section, this view naturally presented itself to me as it had been mentioned in connection with the old-world parasite, but on careful investigation I found that children were sometimes falsely accused of eating dirt simply because they presented this appearance of profound anemia which is seen in those who acknowledge the habit of dirt eating Also I found that those who do eat dirt usually select a special kind of clay on the side of some bank, and which is remote from any source of infection with the larvæ This fondness for dirt is simply the perversion of the appetite produced by the disease, and has nothing to do with the production of the disease

---

* Read at the Fifty fifth Annual Session of the American Medical Association in the Section on Pathology and Physiology and approved for publication by the Executive Committee Drs V C Vaughan Frank B Wynn and Joseph McFarland

[1] THE JOURNAL A M A, Sept 19 1903

The food is usually bolted down in large masses which may pass through the alimentary canal undigested

In this severe type of the disease the patient sometimes becomes so weak that he is scarcely able to drag himself about the house, and there is general edema, which is especially marked about the feet, legs and abdomen He may remain in this condition for some time, and then begin to gradually improve, or he may gradually get worse and worse until he dies These cases have puzzled the physicians in the past, as they were unable to account for the cause of death When this bloated stage is reached, life seems to hang by a mere thread, but many cases which have recovered from the disease give a history of having passed through this condition

DIAGNOSIS

A positive diagnosis of the disease can only be made by finding the eggs of the parasite in the stools of the patient

In the mild type of cases there is absolutely nothing in the appearance of the patient that would lead one to suspect the presence of the disease, and there are no diagnostic subjective symptoms, in cases of the second type this is almost equally as true At best, you may be able to detect a slight paleness of the mucous membranes, but of course this does not make a diagnosis

The severe type presents all the symptoms which we may find in all cases of profound anemia, but these symptoms vary somewhat with the severity of the attack, and there is nothing positively distinctive about this anemia which separates the disease from the profound anemias due to other causes If anyone should stake his reputation on his ability to differentiate the severe type of this disease from profound anemia due to other causes he would be sure to come to grief

There is an important point on which I wish to lay great stress Where one finds one case of the severe type of the disease, one will find a much greater number of the mild and medium types The severe cases are far in the minority, and represent only a small proportion of the great mass of cases of all types of the disease Usually one does not find more than one case of the severe type in one family, and yet all the other children may be infected, and not be suspected on account of having the mild or medium type and not presenting any pronounced symptoms Too much stress has been laid on the severe type to the almost entire exclusion from consideration of the milder types, with the result that the physicians are not on the lookout for the disease unless they see these symptoms of severe anemia The symptoms presented in these severe cases, however, are simply the conditions which would be found in any profound anemia due to other causes, and are not diagnostic of the disease

Until recently all these cases of extreme anemia delayed development, parchment skin, etc have been called malarial cachexia, and treated as such, but now as soon as a physician gains some knowledge of uncinariasis he is prone to call all these cases hookworm disease and proceeds blindly to dose them with thymol and then is surprised because he does not always get results The pendulum always swings from one extreme to the other, but eventually it will settle on rational middle ground.

While it is true that the doctor who makes a snap diagnosis and calls every case of profound anemia uncinariasis, will be correct in the majority of instances on account of the prevalence of the disease, yet he will be surprised at the number of times that he is mistaken and his treatment of no avail This being the case, no doctor is warranted in indiscriminately prescribing the large doses of thymol without first being sure of his diagnosis, and especially so in view of the fact that a positive diagnosis can be made with such ease and accuracy

THE DISEASE NOT CONFINED TO THE LOWER CLASSES

While this is a disease of the country and not of the city, and is most commonly found among the lower classes, yet I find it occasionally in the better classes and in the cities, and often in the most unexpected quarter Every physician must be always on the alert if he would be sure that no case slips through his hands undiagnosed, and which may be disguised by an attack of some other disease

This applies not only to physicians in the south, but also to those in other sections of the country who encounter patients who have lived in the south It is the joy of every boy, whether rich or poor, to go barefoot in the summer and to paddle about in the mud, and many who live in the cities spend their summers in the country, and while there contract ground itch, and in this way have the mild or medium type of the disease

PRECAUTIONS IN REGARD TO THE USE OF THYMOL

Every physician in treating this disease must bear in mind that 5 grains is ordinarily considered to be the maximum dose of thymol, and that in administering 30 grains he may be giving a toxic dose In the old world, death occasionally follows the administration of this large dose, and therefore, it behooves physicians in this country to be extremely cautious in the administration of this drug The treatment should be modified to suit the individual case, and every precaution taken against bad results No physician in this country wishes to be the first to have a death from the administration of thymol, and no physician is warranted in giving thymol without first making a positive diagnosis

HATCHING THE EGGS OF THE UNCINARIA

To hatch the eggs of the uncinaria, I have found that the best plan is to employ a Petri dish with a snugly fitting top Place in this a small amount of soil, just sufficient to cover the bottom of the dish, and add to this soil the feces containing the eggs of the uncinaria The feces should first be rendered semi-liquid with water, so as to facilitate thorough mixing with the soil On adding a small amount of the feces to the soil and thoroughly mixing it, the odor of the feces will disappear, leaving only an odor of damp earth The feces are added gradually until a faint odor of the feces remains, but this will disappear in a day or so (Fig 1)

To facilitate the rapid hatching of the eggs, there should be just sufficient moisture in this mixture to keep the soil damp If too much moisture is present, the lid of the dish may be left off for an hour or so to allow the excess of moisture to evaporate It is necessary to replenish the moisture every two or three days by adding a few drops of water at a time If there is not too much moisture, and the soil is thoroughly mixed with the feces, all of the eggs will hatch in about twenty-four hours Otherwise some of the eggs will not hatch until several days after the first larvæ appear Figure 1 shows Petri dishes with soil containing larvæ

OBJECT OF USING PETRI DISHES FOR HATCHING EGGS

By employing these Petri dishes we can watch the hatching of the eggs and the development and habits of the larvæ This is done by inverting the dish and placing it under the 2/3 objective of the microscope

One can watch the eggs hatch and observe the larvæ traveling about in the soil by their sinuous motion, and in the same way working their way across the open spaces on the bottom of the dish These open spaces may seem to the naked eye to be free from water, but with the microscope we can make out a thin film of moisture, just sufficient to preserve the vitality of the larvæ and favor their locomotion

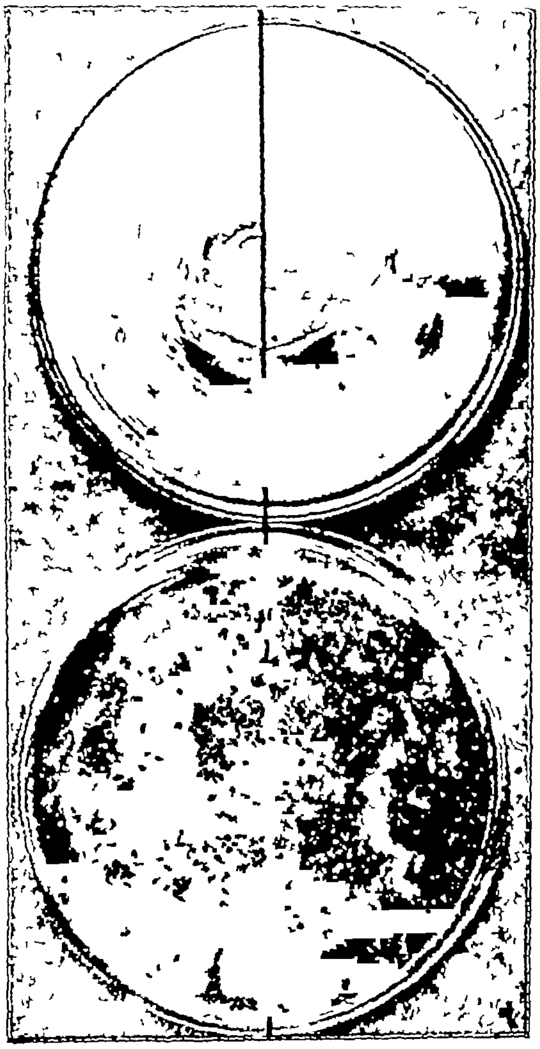

Fig 1—Petri dishes containing soil with larvæ of uncinaria.

APPEARANCE OF THE YOUNG LARVÆ

When the egg hatches, the small larva which emerges seems to consist principally of esophagus and stomach, the other end of the organism being short in proportion At this time the larva is very sluggish under all conditions, and no amount of disturbance seems to arouse it For the next three or four days it grows very rapidly, this growth being most marked in the posterior half of the organism Also at this time the first sheath appears, and with it the organism becomes extremely lively at times, especially if disturbed Whether it is necessary to disturb the larvæ to produce this animation I am at present uncertain, but I am sure that sometimes very little motility is displayed by the organisms while in the Petri dish, yet if placed on a slide they will begin squirming about at a lively rate This rapid movement will last from a few minutes to half an hour or more, and then they will lie perfectly still for a corresponding length of time with their bodies perfectly straight, after which they resume their lively motions When lying still, one who is not familiar with this trait would suppose them to be dead, but close observation will readily differentiate them from the dead larvæ

When placed in a drop of water on the slide there is a tendency to migrate to the edge of the drop, where they squirm about as if trying to get beyond its confines The larvæ may be kept alive in the Petri dish for three or four months After keeping them for some time, however, I noticed that there was a diminution in the number present in the soil, and was somewhat puzzled to know what had become of them, as I was unable to find sufficient remains of dead larvæ to account for the decrease Recently some of the internes at the Grady Hospital called my attention to the fact that on examining some cultures which I had left at the hospital, they had observed great numbers on the underside of the lid of the dish, and that in a good light they could faintly make out these larvæ with the naked eye I found both these reports to be true The precipitation of moisture can readily be seen on the under surface of the lid of the dish, and on examining this the larvæ can be made out, some moving around, while others are perfectly still in the resting stage

SOME OBSERVATIONS OF THE LARVÆ

If larvæ three days old are placed in a drop of water on the slide, it will be observed that while their motility is something wonderful as they thrash about in the water, yet they are unable to make any progress because the water does not offer sufficient resistance to their sinuous movements However, if placed in a thin layer of soil (so that they can be easily seen with the microscope), their sinuous movements give them wonderful speed with the foothold which they gain by zigzagging between the grains of sand or particles of earth As they dart about it may also be noticed that when they encounter anything which blocks their progress that the head remains more or less fixed against one point and the violent motion of the body gives the appearance as if it were trying to force its way If the larvæ are in water their most vigorous efforts produce very little effect on the obstruction, but if there is sufficient soil against which they can brace the body, as it were, they sometimes brush aside the obstacle, or force their way through small openings

Bearing these observations in mind it can readily be seen that it would not be easy for the larvæ to force their way into the ducts of the glands when they are applied to the skin in water, but if they are applied mixed with soil, their power of penetration would be greatly increased

Ground itch nearly always starts between the toes When a barefoot person steps in mud it is forced up between the toes where the skin is thin and tender, and the pressure of the adjacent toes holds the soil in direct contact with the skin, and the conditions are thus made favorable for the passage of the larvæ from the soil to the skin

VITALITY OF THE EGGS AND DEVELOPMENT OF THE LARVÆ

In determining how these larvæ get into the body it is necessary for us first to know where they exist in the natural state To ascertain this we begin with the passage of the egg from the adult worm We find that this parasite is practically confined to the human family, that when matured it is located in the small intestines, that the eggs are discharged from the body in great quantities with the feces, and that these eggs hatch when mixed with damp soil However, if these eggs become dried their vitality is destroyed, they are also killed by freezing When the eggs do hatch we find that this takes place in about twenty-four hours if the weather is warm, but more time is required if the weather is cool

As before stated, the larvæ are very sluggish when first hatched, but gradually become more active, especially if the temperature is favorable, and are extremely lively by the time the first sheath appears, but they again become sluggish and inactive if the temperature is lowered, and a freezing temperature kills them

WHEN GROUND ITCH IS CONTRACTED

From a consideration of these facts we would naturally deduce that, if they do gain access to the body by way of the skin, this must take place during warm rainy weather, or in places where the ground is constantly moist. If a careful clinical investigation of cases of ground itch is made, it will be found that it always occurs as a result of wading about barefoot in the mud, and especially if it has been raining for more that a day previously

SYMPTOMS OF GROUND ITCH

The first symptom of true ground itch is an itching, usually between the toes, and this becomes more and more intense until it is excruciating Children often cry all night during an attack The itching begins immediately after wading in the mud, and small hyperemic spots or macules are noticed at the points of irritation, and these macules appear to be slightly elevated, but hardly reach the distinction of papules These macules rapidly change to vesicles, which may become confluent, forming large blisters, and at the same time there is usually considerable swelling in the underlying tissue The vesicles are usually ruptured, presenting a raw oozing surface This condition may last only a couple of weeks, or it may last several weeks, it may involve only a small area, or it may cover both feet, and the patient be unable to walk about for the time being

CHANCES OF INFECTION

The next point to be considered is, what are the chances for human beings to come in contact with the larvæ? If all the feces of people who have the parasite in their intestines were destroyed, then there would be no possibility of the eggs hatching, and reinfection or infection of others would not take place From a study of the habits of the people we find in the country and in small villages that the feces, instead of being passed into receptacles and carried away, are deposited about indiscriminately on the ground, very often near the house and even in the yard In many instances, if all the eggs passed in the feces of the people living in one house (usually most of the members of a family have the disease) should retain their vitality and hatch out, then the soil of such premises would be swarming with the larvæ, and everyone barefoot would be almost sure to come in contact with the larvæ every time they stepped on the ground However, when we remember that all eggs and larvæ are destroyed when they become dried or frozen, we would not anticipate any danger of infection from the larvæ except when the ground is kept moist in warm weather, and therefore, the feces which furnish infection are only those which are passed just preceding rainy weather in the summer Nature provides for the production of countless numbers of the eggs at all times, so that when a favorable time presents itself there is sufficient material for the propagation of the species

PROPHYLAXIS OF THE DISEASE.

If we thus understand just what conditions are necessary for the completion of the life cycle of the parasite, and can interpose a complete obstruction or break in the chain at one point, then we can readily prevent the disease As all the evidence points to the view that these larvæ pass into the system through the skin of the feet, and that this takes place only during periods of rainy weather or from damp soil, then if we protect the feet so that they can not come in contact with the soil, *we can thus prevent infection. To attempt to* change the habits of these people and to control the deposition of the feces is not a feasible undertaking, as any one who is familiar with the conditions well knows It is much more practicable to teach the people that ground itch is not such a simple disease as they suppose, but that it has serious results, and if they once realize this they are more apt to see that the feet are protected in rainy weather If this is thoroughly carried out, other precautions are superfluous

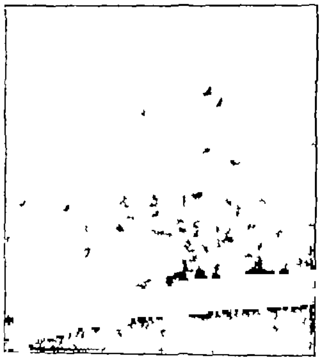

Fig 2—Eruption on the wrist produced by larvæ of the uncinaria

EXPERIMENTS WITH THE LARVÆ ON THE SKIN

Soil containing larvæ twenty four hours old was placed on the back of the wrist of a patient and allowed to remain one hour No effect was produced and no disturbance of the skin followed

When these same larvæ were four days old the soil was again applied to the wrist, covering an area about two inches in diameter, and allowed to remain one hour The soil was bound on the wrist with gauze bandage. Within a few minutes after being applied the patient complained of a slight itching, but I thought this might be due to the irritation produced by the grains of soil being bound on the wrist. However, within eight minutes after being applied he complained of a decided stinging sensation as if produced by very fine needles, and this persisted during the time the soil was in contact with the skin, but subsided somewhat afterward. On removing the soil the area covered by it was found to be decidedly reddened in spots, and these spots or macules appeared to be slightly elevated The macules persisted, but the patient said that he did not experience any inconvenience during the balance of the day, the next morning, however, he found that he had scratched it during his sleep, and I found that the epithelium had been scratched from some of the spots, which were now so elevated as to resemble papules, and the entire area was decidedly swol len The wrist was wrapped with gauze bandage so as to prevent the patient from scratching it

The second morning the patient reported that the itching had been so severe during the night as to seriously interfere with his sleep, and on removing the bandage the area was found to be much swollen and covered with vesicles

The third morning the patient reported that his sleep was again disturbed by the itching, but that it was not severe during the day The swelling had increased and involved the back of the hand

The fourth morning the swelling had extended to the fingers, and inflamed streaks appeared above the wrist, running around to the middle of the flexor surface of the forearm and slightly tender on pressure Axillary glands were somewhat enlarged and tender The epitrochlear was not involved There was very little swelling above the wrist The itching was still troublesome, but temporary relief was obtained by placing it in very hot water

On the fifth day the vesicles were much enlarged and confluent Some had ruptured and saturated several layers of the gauze bandage with the serum The itching was still constant, but not so intense The swelling of the hands and fingers greatly increased No increase of tenderness of the axillary glands or redness of the middle of forearm

On the sixth day the tenderness and swelling were less marked

By the seventh morning the vesicles had begun to dry up and from this time on the swelling subsided rapidly and was all gone by the twelfth day (Fig 2)

With the exception of the disturbance caused by the itching and swelling, the patient said he felt all right During all this time it was noticed that there was very little tenderness over the infected area

On the eighth day the patient developed a severe pharyngitis tongue heavily coated, pulse rapid, headache, aching of body and limbs temperature 102, complete loss of appetite, very weak, said he felt very much like he had the grip

Patient was in bed twenty four hours and after that his condition returned to normal, except that his appetite was not very good and he complained of an uneasy feeling about the stomach His appetite improved rapidly, but he complained for three or four weeks of his digestion being bad, and during this time the patient said he would be waked early every morning by a dull, sickening ache about the stomach After the fourth week all these symptoms disappeared

I was in doubt as to whether this pharyngitis had any connection with the infection However, I recall that in working with the parasite found in the dog, that in administering the larvæ in capsules to a patient, that one of the capsules broke in his mouth and for several days afterward he was troubled with a severe tonsillitis and pharyngitis

At the time the soil was placed on the wrist of the patient the stools were carefully examined, and twice a week thereafter The examinations were negative until the middle of the seventh week, when the eggs of the uncinaria appeared in the stools This was the middle of April and the patient was still passing the eggs the first of June The preliminary report of this case was presented before the meeting of the Georgia Medical Association in April

Following this experiment a small bit of soil containing larvæ, also a drop of water with larvæ were placed at different points on the skin of the patient to determine whether any difference could be noticed in the effect of the larvæ under the two conditions In eight minutes the patient complained of the stinging sensation at the point where the soil had been placed The soil was immediately removed and the skin was found to be reddened and the itching continued Thirty five minutes after the drop of water was placed on the skin the stinging sensation was felt at that point It took nearly five times as long for the larvæ in the water to gain a foothold It was also noticed that the eruption appeared only around the edge of the drop where the water had begun to evaporate and had deposited a thin layer of sediment and this had acted apparently as so much soil in giving the larvæ a foothold This is in accord with previous conclusions that the larva would not pass readily from water into the skin

Again, on a patient who applied for circumcision a small bit of soil containing larvæ was placed on the prepuce The patient seemed to have an idea that it was some medicine preparatory to the operation, as nothing was said to him about it, and in four minutes he remarked that the prepuce felt as if a fly was crawling over it, and a minute or so later said that it felt as if needles were sticking in it On removing the soil the slightly elevated macules were present as in the other cases After circumcision the prepuce was hardened, infiltrated with celloidin and sectioned, but I failed to find the larvæ I was unable to account for not finding the larvæ, and the experiment was repeated recently with like result on the patient, and the tissue is now being infiltrated with paraffin, and report will be made later

To obtain some idea as to how rapidly the larvæ migrated toward the skin, some soil containing larvæ was placed on the skin and allowed to remain four minutes and then removed and spread out on a slide and examined under the microscope No larvæ were found in the soil, and the skin was then placed under the low power and was found to be covered with the larvæ at the point covered by the soil

The larvæ used in the experiments which were successful were from four days to four weeks old

This is the first report of a successful attempt with the parasite in this country to produce the disease artificially, and demonstrates that the work of Looss holds good with the *Uncinaria americana,* and confirms the views previously presented by me as to the mode of infection of the disease

DISCUSSION

Dr H B Ward, Lincoln, Neb—It is worthy of note that the time observed for the development of the larva in this species is almost the same as the time which was found for the development of the European form The correspondence is all the more striking that we now believe there is a considerable difference between the two species, in fact, it is unfortunate that recent investigators are giving entirely different generic names to the two forms, European investigators agreeing that there is considerable difference between the European and the American form It is difficult to explain the absence of larvæ from the skin in the experiment cited and I should like to ask Dr Smith whether he made sections of considerable areas, and whether he found in those sections no trace whatever of the larvæ and no modification of the skin It is hard to believe that in the case of the skin manifesting the after symptoms mentioned the larvæ should not have been in it The European form was detected under experimental circumstances in the skin of a dog and also in the skin of man in a case of a member that was to be amputated and was experimented on immediately preceding the amputation

Dr Claude A Smith—In response to Dr Ward's remarks I can not say just why I failed to find the larvæ in the sections of the skin The sections presented a decided engorgement of the blood vessels with a tendency toward exfoliation of the outer layers of the epithelium I was surprised not to find the larvæ but I feel that this will be an easy matter in the future, just as at first I was unable to infect the skin with the larvæ I first tried to infect the skin of a dog with the larvæ of the dog parasite, which are much more vigorous than the larvæ of the human parasite but did not succeed Now I find that I have no difficulty whatever in infecting the human skin with the larvæ of the human parasite Any one can do this with the larvæ three or four days old if they will add just sufficient moisture to make sure of the contact of the soil with the skin In making one of the experiments I found that some of the damp soil had accidentally dropped on the skin in places not intended to be inoculated and no result followed, as there was not sufficient moisture to bring the soil in close contact with the skin You will thus see on how small a point can depend the success of an experiment I may find that the failure to find the larvæ in the first case was due to some faulty technic in preparing the sections. However, as I had time to examine only one specimen before leaving home, I was hardly ready to make a report on this part of the experiments. The principal part of my paper was to report the artificial production of the disease by placing the larvæ on the skin, the finding of the eggs of the parasite in the stools being proof of the success of the experiment, in view of the fact that the patient did not have the disease previously.

LINEAR NEVI

A FEW CLINICAL AND PATHOLOGIC CONSIDERATIONS IN REFERENCE TO NEVI IN PARTICULAR AND TO DERMATOLOGY IN GENERAL.*

M. L. HEIDINGSFELD, M.D.
CINCINNATI

Inasmuch as the entire subject of nevi is still a dermatologic dark Africa, and linear nevus forms an intricate and obscure division, I will endeavor to confine myself in this paper to a few brief, chiefly histologic considerations, and their application to linear nevi in particular and dermatology in general. So many anomalies, e. g., pigmentations, albinism, hirsuties, angiomata, teratomata, keratomata, atheromata, port-wine stains, defects, etc., are included under the technical term nevus, that it is unfortunate that its original lay character should have acquired scientific value. Additional confusion has attended this unfortunate interchange of terms, by the fact that identical lesions escape classification if their distribution is general instead of limited, and that their development need not be coincident with birth, but months or even years after. Linear nevi not only share in the confusion which attaches itself to nevi in general, but that due to a verbose redundant terminology replete with almost every variety of dermatologic phrase or term, such as nevus congenitalis, zoniformis, herpetiformis, linearis, papillaris, lichenoid, ichthyotic, eczematous keratotic, pigmented, piliferous, hystrix, nigricans, papillomatous, verrucosus, etc., *to suit almost every variety* of clinical condition. This *unfortunate redundant terminology* has been rendered permissible by the great clinical variations which exist in individual instances, at the same time the general characteristics of the affection are so clean cut and definite and stamp it so individually and unmistakably *that* any great digression in nomenclature appears unpardonable. Additional latitude is likewise afforded by an equally variant histology, and though this special feature of the affection has not as yet been extensively elaborated, enough has already been produced to demonstrate that in this distinctly one affection many *varieties of* pathologic lesions are readily found, making its pathology when strictly interpreted as complex and unintelligible as the clinical history. With all this nevus linearis is a dermatologic affection, *sui generis* possessing a complete entity and *for the most part* a very easily recognizable identity. With these characteristics *it serves* an interesting and instructive example of the foibles and weakness of present dermatology, namely, the tendency to individualize and thereby complicate rather than generalize and thereby simplify single types in classification, and secondly, the tendency to give to dermatologic histopathology a diagnostic rather than mere confirmatory value. In other words, there are many cases in dermatologic literature which are reported as special and distinctive types of affection, by authors who doubtless could readily find a place for them in the already overelastic nosology, if less attention were *directed* to *individual* traits and more to general description.

According to Morrow,[1] the distinguishing characteristics of linear nevus are: 1, Its linear disposition in the form of continuous or broken bands or streaks following the long axis of the limb or transversely on the trunk; 2, its unilateral disposition (with some exceptions); 3, papillary or verrucose character, constituted by a hypertrophy of the epidermal and papillary structures; 4, congenital origin, usually present at birth or several months afterward, rarely not before adolescence; 5, sensory disturbances, such as itching, and usually resulting from external irritation; 6, the affection may *increase in extent, remain stationary, regress or undergo* degenerative or malignant transformation. These features of the affection gathered from the cases from the literature and from Morrow's own cases, present variations, and are by no *means constant. In fact,* the character of the affection is so distinctive that it requires but few of Morrow's characteristics to form a tripod on which the diagnosis can unmistakably and securely rest.

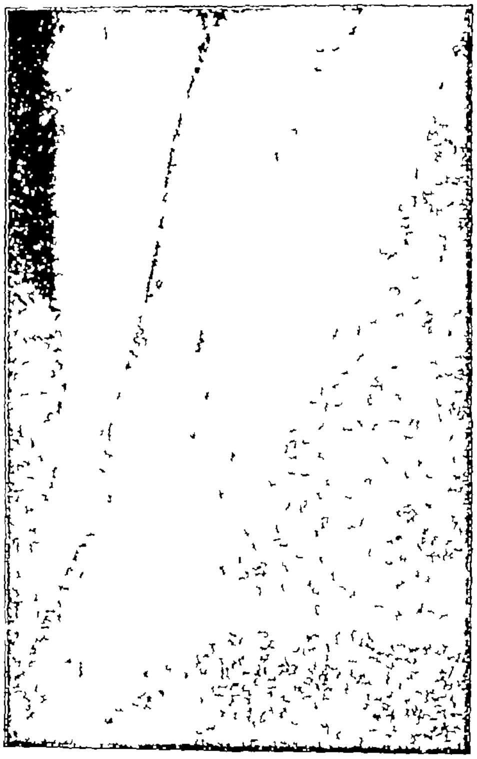

Fig. 1.—Case 1. Linear nevus showing marked spontaneous regressive changes. Dendriform lesions. Photo Jan. 16, 1901.

The following three cases, which were presented to the Cincinnati Academy of Medicine, Jan. 28, 1904, are briefly reported.

Case 1.—(Fig. 1.) W. M., male, aged 20 years. The lesions are firm, hard, papular, somewhat elevated and keratotic, sharply circumscribed in character and brownish red in color. They are sharply limited to the right half of the body, and are distributed in linear form directly over the *great* sciatic nerve, from its point of origin at the ischio *sciatic foramen*, along its entire course, down the *posterior aspect of the thigh*, to its division into the internal *and* external popliteal branches. From this point it is distributed in broken segments along the internal *popliteal* nerve, over the posterior aspect of the calf of the leg, and also along the external popliteal nerve over the external and anterior aspects of the leg, near the fibula The second distribution is over the right half of the penis and scrotum, which are richly covered with a large number of linear filaments, none of which, however, transgress the median line The third distributon is over the right aspect of the forehead and nose and consists of a few relatively faint linear filaments, that are sharply arrested at the median line According to statements of both the intelligent mother and patient, the congenital lesions were not present at birth, but developed a few years later, and have persisted ever since, with relatively little change The only subjective symptom has been an occasional pruritus, but not very annoying in character The objective disfigurement, coupled with the fear that the lesions might terminate into something more serious, induced him to seek medical attention He maintains that his case was never thoroughly understood nor any medical relief afforded until the present diagnosis was established four years ago Figure 1 shows the condition one year later During that year the case showed marked retrogressive changes, the lesions having spontaneously disappeared over the middle third of the thigh The linear distribution and dendritic or branching character of the lesions are well marked in this photograph

---

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Cutaneous Medicine and Surgery, and approved for publication by the Executive Committee: Drs. H. W. Stelwagon, J. A. Fordyce and H. G. Anthony.

[1] Morrow: New York Med. Jour., 1898.

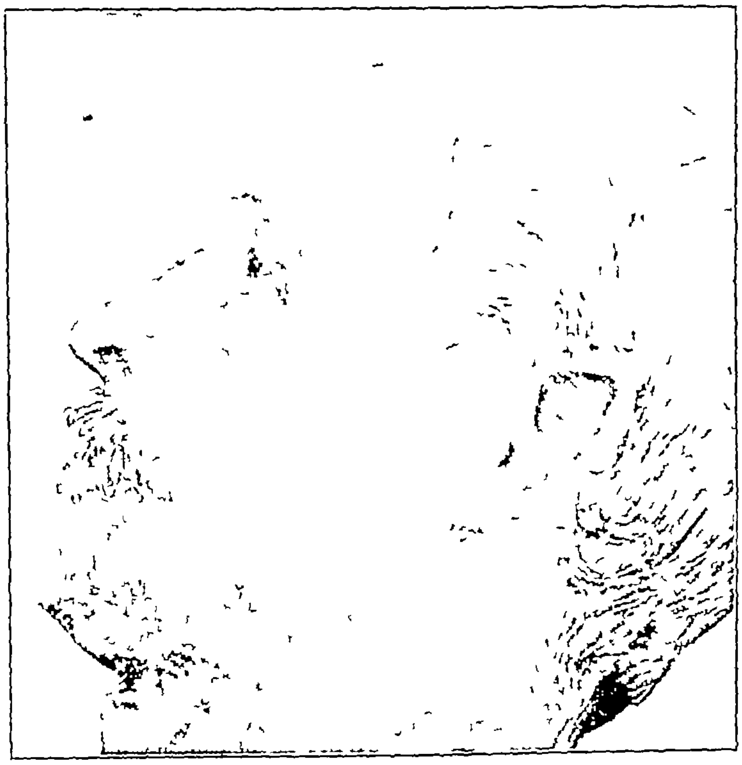

Fig 2

Since then there has been a gradual and spontaneous recurrence of the lesions until the distribution at the present time corresponds closely to the distribution as observed when the patient was first seen It is noteworthy to mention that the lesions always recurred exactly over their former site

Case 2—(Fig 2) J S, aged 38 years, male, presented himself for the first time July 30, 1902, when the accompanying photograph was taken The nevus in this case is situated over the left antero lateral aspect of the scalp, covering a relatively large, irregularly shaped area, not corresponding to the distribution of any particular artery, nerve, metamere, or line of Voight In this case the presence of the nevus dates to the birth of the patient, and was yellowish in color and smooth in character It has remained without material change, with the exception that it has grown decidedly warty in recent years

Case 3—H C, aged 10 years, female, presented herself four years ago, March 12, 1900, with a nevus, present from birth, showing no material change, and with a distribution over the left side of the neck, as recorded by the accompanying photograph (Fig 3) The lesions for the most part were small, papular and sharply circumscribed, smooth, non elevated in character reddish brown in color, and scattered irregularly over the affected area A few were dark and pigmented, on the forehead and scalp the lesions were yellowish in color and preserved a linear arrangement, but were so closely grouped that they formed an irregular, diffused, sharply defined area about the size of a silver half dollar Some of the lesions at the time were successfully removed by electrolysis On Jan 23, 1904, patient presented herself for the second time, when the next accompanying photograph was taken (Fig 4) At this time a material change was noted The former smooth yellowish patch on the forehead had become rough and warty, and was studded with several papillomatous prolongations The lesions over the neck and cheek had greatly multiplied in number and now extended down over the chest in great numbers as far as the nipple The new lesions for the most part were small, sharply defined, darkly pigmented papules, having individually a close analogy to common moles, or, on the whole, a more striking resemblance to the cutaneous metastases of a pigmented sarcoma The unilateral character was still sharply maintained and the median line was not transgressed

If we group these three cases together, the most striking characteristic common to all is congenital origin.

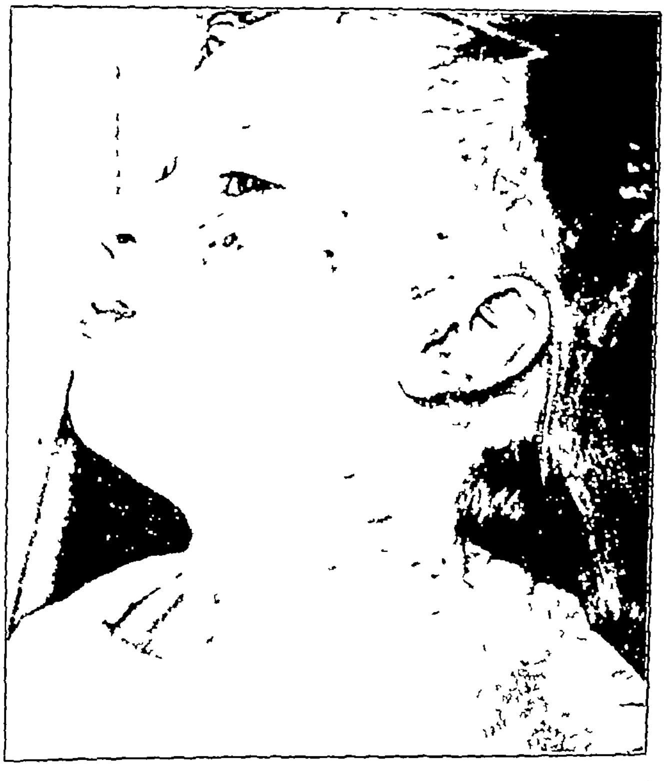

Fig 3—Case 3 Linear nevus of sharp unilateral character with multiform lesions Photo March 12, 1900

Even this character requires in Case 1 the more recent and liberal interpretation of congenital lesions, which the most conservative (Besnier included) are nowadays willing to grant, and that is that their visible appearance need not date from birth, but months or years later By far the vast majority of cases reported in the literature are present at birth or shortly afterward Among those who report a later development are Leven[2] (fourth week), Dyer[3] (sixth week), Ransom[4] (sixth month), Lanz[5] (first year), Werner[6] (first year), Burri[7] (second year), Kobner[8] (second year), Phillipson[9] (second year), Hagen[10] (third year), Gerhardt[11] (third year), Fox[12] (tenth year), Touton[13] (sixteenth year), Dyer[illegible] (seventeenth year), Hallopeau and Jeanselme[14] (twentieth year) Jadassohn[15] (p 372) states that the lesions of this affection are due to general causes, that it is impossible to give to it an anatomic ensemble, and, therefore, the term nevus is an indispensable one

The next most noteworthy feature of the cases is the unilateral distribution of the lesions which, though extremely well marked in two of the cases, is not so apparent in the third (Case 2), because the median line is not approached

Most of the cases in the literature possess a distinctly unilateral character, the lesions in most instances rarely transgressing the median line anteriorly or posteriorly The most prominent exceptions are reported by Dyer[illegible] (3 cases), Pringle[16] (1 case), Spietschka[17] (1 case) Gerhardt[11] (1 case), Ransom[4] (1 case), Kobner[18] (1 case)

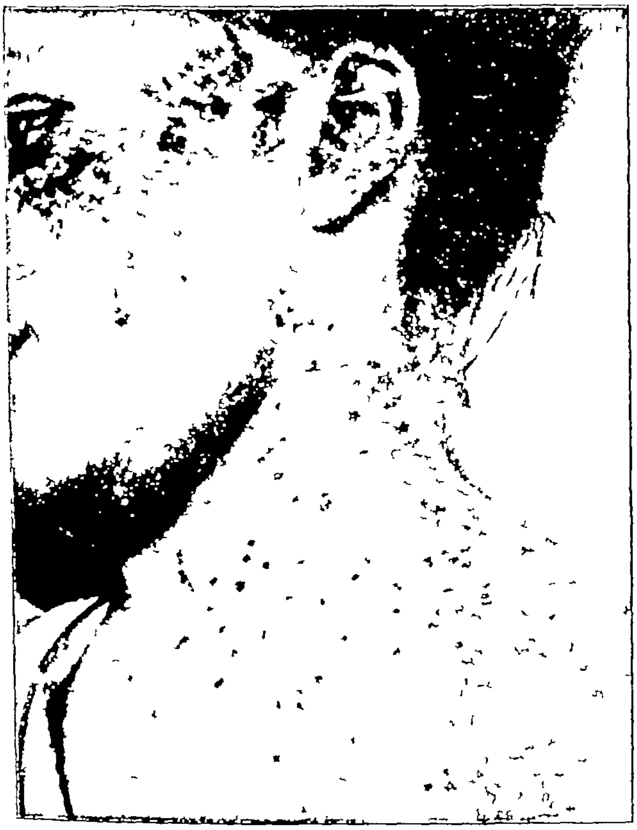

Fig 4—Case 3 Showing great multiplication of lesions in short time. Photo Jan. 23, 1904

The next most salient characteristic is its linear character and disposition,[19] or rather lack of disposition along nerves, lines of Voight, lymph-vessels or other structure

The disposition along structural elements is likewise apparent only in Case 1, and here closely follows, in rather remarkable manner, the great sciatic nerve and its branches

These variations in form and distribution conform with the general report of cases Among those who report a nerve distribution are Saalfeld,[20] Jadassohn[21] (4 cases), Kobner,[18] Simon,[22] Barensprung,[23] Lommel,[24] Etienne[25] (3 cases), Brocq,[26] Campana[27] (11 cases) Among those who maintain a line of Voight distribution are Hagen,[10] Phillipson,[28] Peterson,[29] Galewski,[30] Pecirka[31] Buri[7] Meissner[32] reports a distribution along lymph vessels Lanz,[illegible] Abraham,[33] Pringle[16] and others are opposed to nerve and line of Voight distribution, or any particular form in general (Kaposi[34] states in his text-book "that there is a close relationship between nerves and linear nevi can not be denied from their oft-distinct zoster-like unilateral distribution, and their parallel course over the nerves of the extremities, but an absolute proof is still wanting" He believes that their presence can be more easily accounted for by developmental error than by innervation influences and that the term "nerve nevi" is merely conventional and without neuropathic importance) Galewski[35] reported a case of nevus linearis, with a line of Voight distribution, before a congress of German scientists, at Nuremburg in 1893, and Saalfeld[20] in discussion questioned the character of the distribution, and Galewski in reply admitted that he could not state in the case in question, whether the distribution followed the lines of cleavage, nerves or Voight's lines

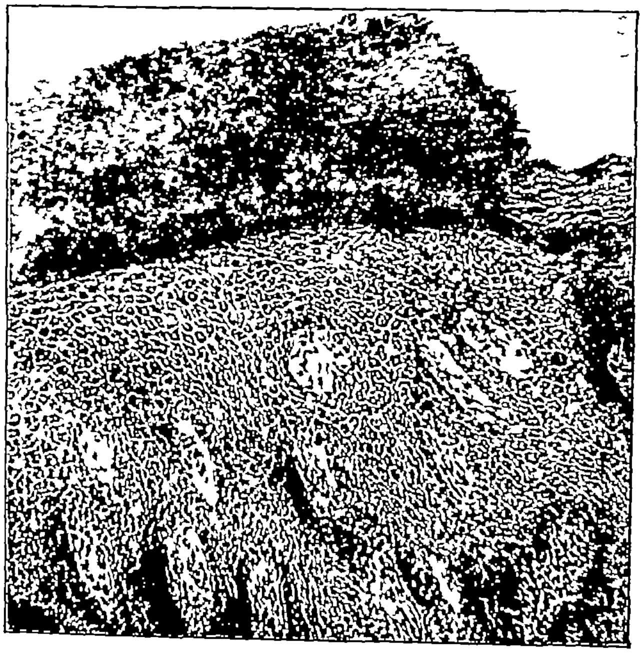

Fig 5—Case 1 Chief pathologic change is heaped up layers of imperfectly keratinized epithelial cells.

The remaining so-called distinguishing characteristics of the affection also showed some clinical variations Stability of the lesions were only marked in Case 2, in Case 1 they constantly recurred and retrogressed, and in Case 3 there was an extensive and rapid development in four years' time Sensory disturbances were entirely absent in two cases, and only slightly (mild pruritus, not constant) present in Case 1 The individual lesions, though for the most part warty and papular, presented wide differences in size, consistency, arrangement and location, even showing almost every degree of variation in one patient (Case 3)

The variations in stability, above mentioned, are frequently encountered in the literature, and reference to specific examples seems superfluous Some marked instances in the clinical appearance of the lesions are instanced by Selhorst,[36] Mendes da Costa,[37] and Thibierge,[38] who report lesions which closely resemble commedones or acne Kobner[8] describes a case with xanthoma-like lesions Jadassohn[39] reports that two of his cases were incorrectly diagnosed pityriasis versicolor Touton[13] reports a case under the name "neurodermatitis linearis chronica,' which is pronounced linear nevus by Jadassohn and Galewski Robinson,[40] on the other hand, reports a case "nevus linearis," which is pronounced by Lutz keloid or papilloma Fox[41] records an apparent case under the name localized ichthyosis Brocq[20] a case as lichen simplex chronicus Hallopeau[14] reports one as nevus linearis lichenoides, which he would have diagnosed, on account of its late appearance (twentieth year), lichen planus, had not the slight prodromal itching ceased entirely Fox[12] reports the lesions of one case as probable myomata Fox,[42] in another case occurring in the scalp, states that many cases of so-called white moles and congenital alopecias are probably "nevi linearis"

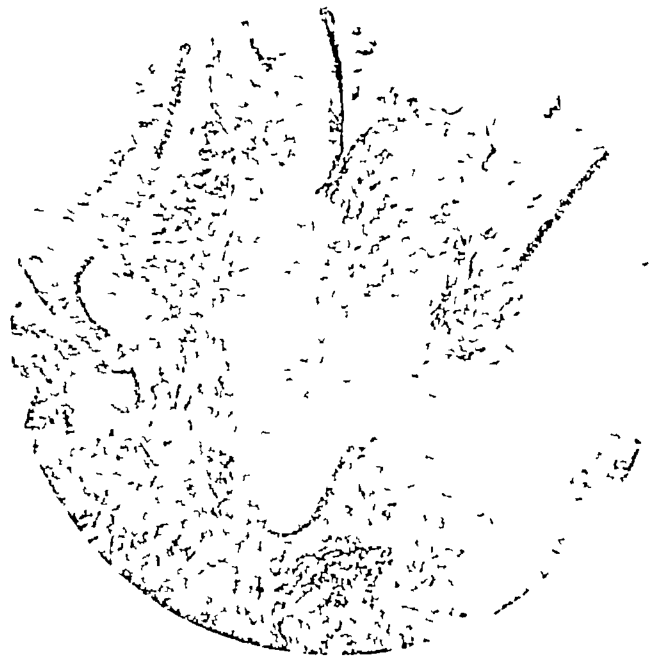

Fig 6—Case 2 Chief pathologic change of this case is a papillomatous structure

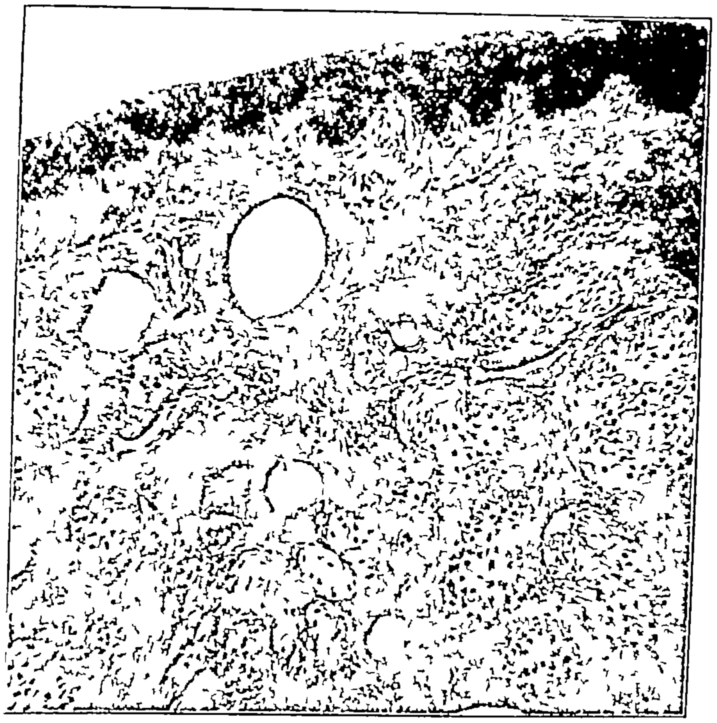

Fig 7—Case 3 Adenoma of the sebaceous glands from yellowish lesion of the scalp

From the foregoing brief clinical descriptions, and the superficial survey of the literature, the very complex diverse clinical nature of this affection is readily apparent And yet in spite of its multifold nature, its burdensome nomenclature, the endless variety of lesions, their obscure and variegated distribution, and their varying stability and instability, there is something to the clinical ensemble that is clear, distinctive and clean-cut, and readily gives the affection an unmistakible identity It is strange to state, that however diverse its clinical history, its histopathology presents a still more diversified character There is scarcely an element of the skin, epidermis, dermis or glandular element that is not involved in some form of pathologic change, stratum corneum, rete spinosum, papillæ, lymph and blood vessels, sebaceous and sudoriferous glands, pigment cells, hair and their follicles are all variously and unequally involved in some form of change Pathologic variations and differences exist not only in separate individual cases of this distinctly one affection but often in one and the same case, so wide in range and sweeping in character as to almost precipitate us in an abyss of histologic agnosticism Not only is there a marked lack of analogy of the lesions for each other, but there exists at times the most striking analogy for affections totally different in character, warts, moles, adenomata, sarcomata, clavus, false and true keloid, xanthoma, etc, are so closely imitated in histologic structure that a discrimination is deceptive, if not impossible

In Case 1 the chief pathologic change (Fig 5) is a hyperkeratosis, consisting at times of a single heaped-up layer of only partially keratinized epithelial cells which, for the most part, retain a fairly well-developed nucleus, at times there are several successive layers of these partially keratinized cells of varying thickness and showing different degrees of keratinization The papillæ of the skin and the interpapillary processes of the rete show a moderate amount of elongation under the hyperkeratotic area, and the involved papillæ show a moderate amount of leucocytic infiltration, commensurate with the corresponding inflammation from simple me-chemical pressure The general histopathologic appearance bears a very close resemblance to ordinary clavus, from which, as far as microscopic evidence shows, it is practically indistinguishable

In the *Journal of Cutaneous and Genito-Urinary Diseases* (Vol xviii, p 195), there is a photogravure in an article on "Leucopathium Unguium"[43] representing a single layer of imperfectly keratinized hyperkeratosis, taken from this particular case Touton[13] reports a case of almost identical histologic structure under 'Dermatitis Linearis Chronica" which Jadassohn and Galewski, in discussion, call 'nevus linearis"

In Case 2 the chief histopathologic change (Fig 6) in the yellowish-white slightly papillomatous hair denuded lesion of the scalp (lesions which Fox[41] states are probably often reported as congenital alopecias or white moles), was a papillary hypertrophy hyperkeratosis and acanthosis, in most respects identical and indistinguishable from the histologic structure of common and venereal warts In other respects there were no important or characteristic changes

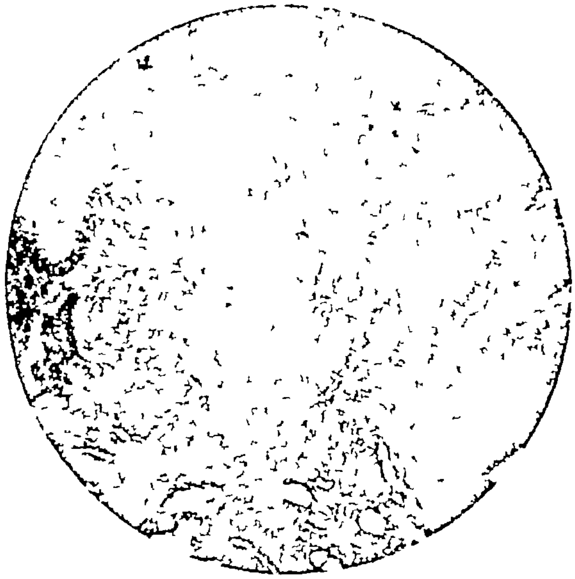

Fig 8—Case 3 Papillomatous structure of warty excrescences

In Case 3 the most interesting and varied pathologic changes are encountered The yellowish-white, hair-denuded scalp lesion, which is analogous in size, color, location and distribution to the similar lesion in Case 2, showed a very extensive adenoma of the sebaceous glands, which consisted of huge masses of lobules, closely crowded together and occupying almost the entire cutis (Fig 7) The structure and nuclei of the sebaceous cells were well maintained The other changes were of slight character and not of noteworthy mention, except a few papillomatous excrescences, which had only recently made their appearance, and which showed the same warty papillomatous structure as Case 2 (Fig 8) This latter applies merely to the excrescences and not to the adenomatous base from which they spring This structural dissimilarity between clinically similar lesions is more striking, by reason of the fact that the lesion in Case 2, according to the patient's history, was originally smooth like that of Case 3, and the papillomatous masses had also likewise been secondarily acquired This observation refutes Jadassohn's[15] dictum that lesions which preserve the same clinical characteristics in Nevus Linearis' also maintain the same histologic structure

Jadassohn[44] reports a similar adenoma of sebaceous glands in two cases of nevus linearis, and states that doubtless many cases reported in the literature, under the names of sebaceous adenomata, etc, can be properly classed with the linear nevi Pollitzer's[45] case, which is reported under the name of 'adenoma sebaceum," can probably be correctly quoted as an example of such incongruity Bandler[46] reports two cases, in both of which the lesions were located on the scalp, and in both of which there were adenomata sebacea, in all respects similar in histologic structure to Case 3 Moeller[47] states that adenoma of the sebaceous glands is one of the forms of histologic change

The lentiginous lesions of Case 3 presented various forms of histologic structure, the firm, glistening, yellowish-red, slightly elevated lesions showed a dense connective tissue hypertrophy which extensively invaded the entire cutis and pars papillaris, filling these structures with a dense meshwork of connective tissue fibers which closely enveloped the few remaining hairs vessels and glandular elements (Fig 9) In general, the histologic appearance closely resembled and was practically indistinguishable from false or true keloid

The slightly elevated, oval-shaped hairy lesions, which in gross appearance resembled ordinary pigmented moles, presented the characteristic histologic structure of these lesions, a moderate cellular infiltration of the papillæ, pigment accumulation and hypertrichosis (Fig 10)

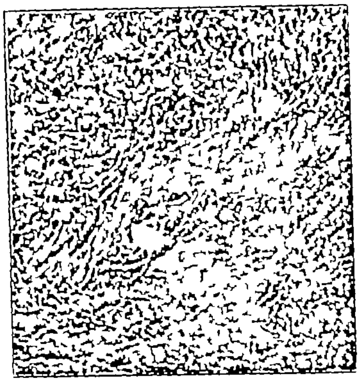

Fig 9—Case 3 Keloid like structure of fibro-connective tissue from a glistening yellowish red lentiginous lesion.

The small round, darkly pigmented lesions, which were rapidly multiplying on the face and particularly on the neck and chest, showed an extensive spindle-shaped invasion of the pars papillaris (Fig 11) connective tissue, numerous thin-walled capillaries, and a marked asymmetry of structure and arrangement that closely resembled and was practically indistinguishable from sarcoma cutis (Fig 12) In this particular case, then, the various lesions show the most marked variety of histologic structure, varying in analogy from sebaceous adenoma to common and venereal warts, false and true keloid moles and sarcoma and if Case 1 is included, the histologic analogy also showed clavus

Other histologic anomalies of linear nevi encountered in the literature, include "Adenoma of the Sudoriferous

[47] Moeller Arch f Derm u Syph vol lxii No 1 1902 p 53

Glands," by Peterson,[29] Elliot,[48] Beier[49] Selhorst[30] reports his case as histologically indistinguishable from acne vulgaris, which affection it also resembles clinically Meissner[32] reports the histologic changes of his to consist largely of proliferated and infiltrated lymph vessels Kobner[50] reports the histologic structure of his case, similar to that of xanthoma, and containing the yellowish-brown pigment of the latter affection, and styles it a xanthoma multiplex nevus Although lesions contain an abundance of connective tissue and vascular elements, he objects to classifying the affection with the fibromata, because he regards the latter as invariably springing from newly formed and not pre-existing tissue The lesions in a case reported by Fox[12] are myomatous, though they apparently lack histologic confirmation Bertamini[51] reports spherical concretions on the surface of the skin, involving the sweat-duct orifices, and containing bodies resembling psorosperms

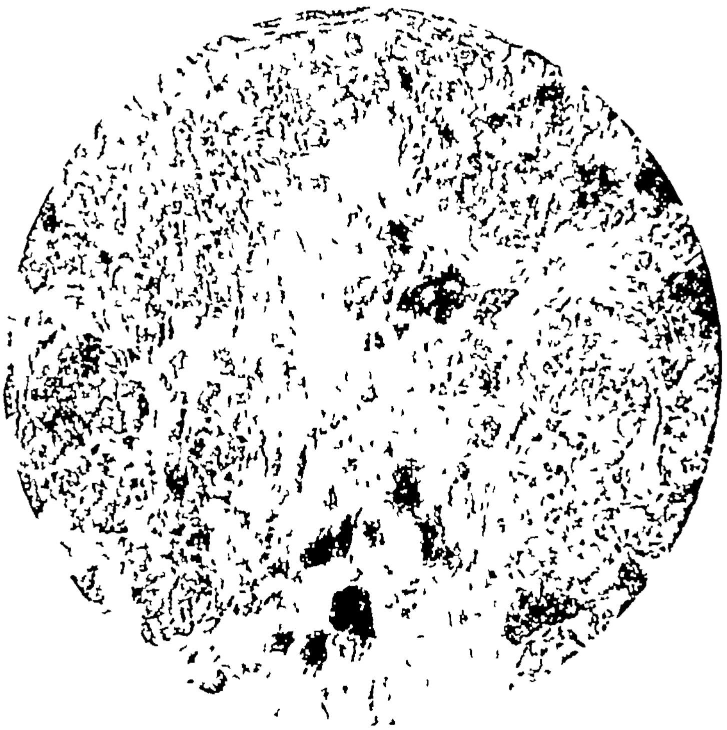

Fig 10 —Case 3 Pigment accumulation from a small mole like lesion

It is evident that linear nevus presents clinical and histologic variations of such complex and diversified nature that if each be given special or undue significance the resulting confusion would readily permit an uncertain and doubtful classification of cases It is this highly developed feature of present-day dermatology which encourages flagrant excesses and causes an unnecessary and unfortunate multiplication of disease Peterson[29] utters the incrimination when he states in reference to this very condition that "it is an example of how many different forms are still gathered together under the collective name of nevus, it is high time to break the frail and elastic bonds which loosely hold together the papilloma, fibroma, adenoma pigmented moles, etc, under a congenital mask, and name each in accordance with its histologic structure" It is the converse of this proposition which is true The present demands that the frail and too elastic bands be not ruptured, but strengthened and reinforced It is their frailty and inelasticity that permits in great measure the unnecessary disparity in the existing classification, and to base its nomenclature on histologic structure would precipitate the affection into an inextricable state of chaos

Brocq[20] reports an apparent case, with a distribution over the small sciatic and external saphenous nerve under "Lichen Simplex Chronicus" Hallopeau and Jeanselme[14] report a case which, on account of its extreme late appearance (twentieth year), they would have diagnosed "lichen planus," had not the slight prodromal itching ceased later entirely Robinson[52] reports an apparent case as "lichen planus," and Lutz calls a case presented by Robinson "keloid," or "papilloma," and takes exception to the term nevus unless applied too strictly to vascular lesions Touton[13] reports a case as 'neurodermatitis linearis chronica," which Jadassohn and Galewski pronounce "nevus linearis" Spiegelberg[53] describes a typical case under "Congenital Papilloma," and another under 'Localized Ichthyosis" Flittner[54] describes a case under "Ichthyosis Cornea," Leven[2] under "Dermatitis Linearis Neuropthica," and Lommel[24] reports two apparent cases under "Chronic Zoniform Eruption," and Bertamini[51] a case as "Linear Disease"

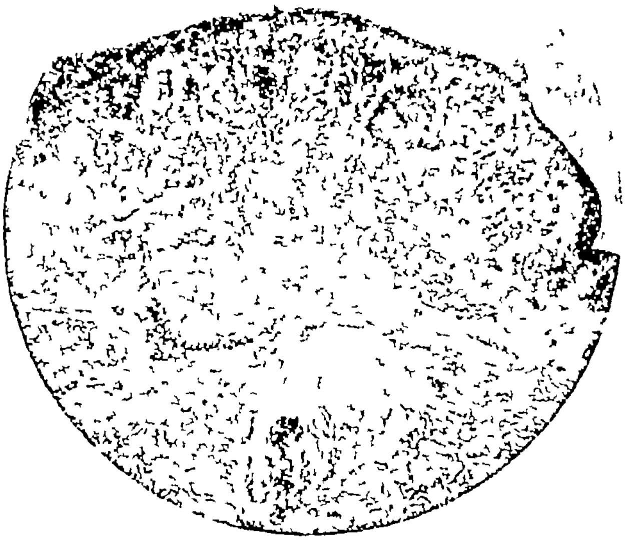

Fig 11 —Case 3 Extensive cellular infiltration and epithelial proliferation resembling sarcoma from one of the rapidly multiply ing pigmented lesions

This affection well illustrates that reformed dermatology of the future should strive for a simpler and more collective classification It also aptly illustrates that the efforts of Phillipson[55] and others[56] to establish a reformed dermatology on purely histopathologic genetic basis is hopeless and insuperable [43] Jadassohn Unna[57] and Peterson have all made vain efforts to establish linear nevi on a purely histopathologic basis Unna[57] states that he "strove to establish the conception of nevi on a series of purely anatomic considerations The discovery that new growths pass through a very peculiar development, in which the first and last stages differ so materially in histopathology, revealed that this was an utterly impractical measure" He[8] also states that if nevi lineares are topographically similar and clinically and histopathologically different, they are not an entity, and can not be collectively grouped with nevi, and this very affection will form the starting point for an entire new study of the nevus question

My personal impressions lead me to believe that these differences virtually exist and though their explanation is not forthcoming, it is both dangerous and fallacious to establish solely for such reason new types of affection Any three or more characteristics as tabulated by Morrow or gleaned from carefully reported and well-observed cases, is a sufficient tripod to rest a secure diagnosis The affection exquisitely demonstrates the unreliable aid of the microscope, yet Unna admits that he would have diagnosed one case a chronic eczema had not the organism been absent Magnus Moeller[17] reports a case, the diagnosis of which wavered between linear nevus and lichen planus, until firmly established by the microscope and Bertamini[31] reports a case whose clinical diagnosis was lichen planus, and the histologic linear nevi I do not believe that our present histopathologic knowledge, in spite of assurances to the contrary, has advanced to such a degree that the exact nature of a disease can be readily determined by mere pathologic examinations If the greatest conflict of opinion arises at times from the mere description of a cell (Plasma Cells, Unna, Marschalko,[59] Neisser,[60] Jadassohn, Almkoist,[61] et al) it is not suprising that an utter lack of uniformity should attain in the histologic considerations of general conditions, attributable to more than a varied location, duration secondary changes, therapeutic influences and technic In the effort to give histopathology its greatest degree of importance, it is being robbed of much practical value by imparting to it too much intricate detail With all its classic interest and all its intrinsic worth nevus linearis clearly illustrates that it possesses at best mere confirmatory value

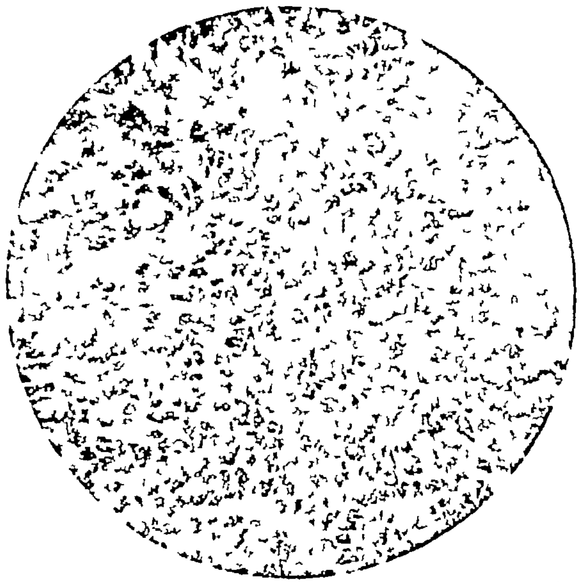

Fig 12—Case 3 Same as Figure 11 strongly magnified showing character of cellular infiltrate

To briefly recapitulate, linear nevus is a dermatologic affection, for the most part easily recognized as a type of *sui generis*, possessing an unmistakable identity Great variations in clinical appearance, location, duration, distribution, development and secondary changes have permitted an endless amount of unnecessary confusion in classification, and an unfortunate redundant nomenclature It also possesses an exceedingly varied pathology Great disparity in histologic structure exists between lesions that are clinically similar, great disparity exists between lesions in close proximity from the same patient, a deceptive histologic resemblance often exists between lesions of linear nevi and types of dermatologic affection, totally different in character The affection aptly illustrates some foibles of present-day dermatology, namely, the tendency to individualize and thereby complicate, rather than generalize and thereby simplify single types in classification, and secondly, to give to dermatologic pathology an inflated diagnostic rather than a mere confirmatory value

THE UNITED STATES PUBLIC HEALTH AND MARINE-HOSPITAL SERVICE

PART II—THE SERVICE AS IT IS TO DAY

(*Continued from page 547*)

(A) ORGANIZATION OF THE BUREAU

The Bureau of Public Health and Marine-Hospital Service forms a part of the Treasury Department, and is presided over by a surgeon general

For executive administration, the bureau is divided into six principal divisions, each presided over by an assistant surgeon general, as follows

Division of Marine Hospitals and Relief, Division of Domestic Quarantine, Division of Foreign and Insular Quarantine, Division of Sanitary Reports and Statistics, Division of Personnel and Accounts, Division of Scientific Research There is also a Miscellaneous Division presided over by an assistant surgeon

DIVISION OF MARINE HOSPITALS AND RELIEF

To this division are sent all matters relating to the marine hospitals, 22 in number, owned by the service and to the patients, numbering 58,000, treated annually in these hospitals, and in some 122 relief or contract stations The purveying depot, a large building located in New York, is under the direction of this division, to which are also referred all matters relating to hospital supplies, including subsistence, drugs, hospital furniture, surgical instruments and appliances, plans and specifications for hospital construction, and the conduct of the sanatorium for consumptive patients at Fort Stanton New Mexico

DIVISION OF DOMESTIC QUARANTINE

This division has in charge all matters relating to the national maritime quarantine stations, embracing 19 complete disinfecting stations and 18 inspection stations At the former are hospitals, barracks, disinfecting machinery, steamers and small boats, all requiring constant care and attention This division also must see to the expenditure of appropriations for new stations, involving purchase of lands, construction of piers and buildings, said construction being generally under the supervising architect of the Treasury on plans approved by the bureau and the department but occasionally the bureau attends to this construction itself

58 Unna Monats f prak Derm xii p 296 xx p 477 Report of Deut. Naturforch

59 Marschalko Arch f Derm u Syph xxx, p 3

60 Neisser Arch f Derm u Syph xxxi p 387

61 Almkoist Arch f Derm u Syph lviii p 91

All matters relating to the quarantine regulations and their interpretation, matters relating to interstate quarantine and suppression of epidemic diseases, as well as quarantine on the Mexican and Canadian borders, are handled through this division

DIVISION OF FOREIGN AND INSULAR QUARANTINE AND IMMIGRATION

To this division is assigned the management of the national quarantine stations in Hawaii, Porto Rico, and the Philippine Islands the supervision of officers detailed for duty in the offices of the United States consuls in foreign ports who, with the consuls, sign the bills of health, and all matters pertaining to the *medical inspection of immigrants*

DIVISION OF SANITARY REPORTS AND STATISTICS

This division is charged with the preparation of the *Public Health Reports,* published weekly by the bureau, and all matters of a statistical nature are referred to this division

DIVISION OF PERSONNEL AND ACCOUNTS

This division has supervision of all matters relating to the personnel of the service, examinations for admission to the corps of commissioned officers, examinations for promotion, appointments and resignations, appointment of boards for the physical examination of officers of the Revenue-Cutter Service This division has also charge of the bookkeeping of the service

DIVISION OF SCIENTIFIC RESEARCH

To this division are referred all matters relating to the hygienic laboratory, as well as requests for scientific investigation of special diseases as, for example, the recent investigation of the so-called spotted fever in the Bitter Root Valley, Montana The initiatory steps for special investigations of this character are taken in this division, but any prolonged or technical work connected therewith is turned over to the laboratory

Requests for special investigations of water pollution or local causes for the spread of typhoid fever are referred to this division

The officer in charge of this division examines all current literature relating to scientific medicine or sanitation, and keeps a card index of the same

MISCELLANEOUS DIVISION

This division has charge of the mailing of all bureau publications, and certain miscellaneous duties relating to the reports of necropsies from the marine hospitals, the medical examination of claims for benefits on account of injuries received by the crews of life-saving stations, certain matters relating to the annual report etc

ITALY AND THE GREAT ANTIMALARIAL CAMPAIGN

(*Continued from page 549*)

LEWELLYS F BARKER MD

CHICAGO

BERLIN, June 25, 1904

The medico chirurgical division of the R Instituto di Studi Superiori at Florence has a strong faculty though not all the members of the faculty live in Florence some of them holding professorships also at Pisa, Siena, Modena, Genoa or Cagliari Grocco is the distinguished clinician there, he has an immense consultation practice, drawing patients from great distances in the country round Guido Banti has the chair of pathologic anatomy and Eugenio Tanzi that of psyschiatry Ottone Barbacci, who has written so many thorough collective reviews for the *Centralblatt f allgemeine Pathologie,* lectures here on pathologic anatomy, though he is professor in Siena Gino Galeotti, too, who contributed the much commented on article in the last volume of the *Zeitschrift fur physiologische Chemie* on the precipitation of albumins with metals, bringing the whole process under the "phase rule" of the great New Haven physicist, Gibbs, lectures here on general pathology, though his regular chair is at Siena

The insane asylum under the direction of Professor Tanzi lies some distance outside the city Excellent work is being done there, both in the wards and in the laboratory Dr E Lugaro, the editor of the very progressive *Rivista di patologia nervosa e mentale,* is one of the most active members of the staff I enjoyed much seeing the original preparations on which his publications regarding experiments on the spinal ganglia and posterior roots of the spinal nerves are based Just now Lugaro is analyzing all the cases of dementia precox (in the sense of Kraepelin) which have been met in the asylum, his article should form a valuable contribution to our knowledge of this remarkable disease

It is to be hoped that in the revival of all interests now noticeable all over northern Italy that Florence will regain some of its former intellectual prestige Its past history would indicate that there must be something extraordinary in the local conditions there In how far, however, the *genius loci* was responsible for Dante, Giotto, Fra Angelico, Benevenuto Cellini, Michael Angelo and Savonorola, it is hard to guess Whether or not the city that did so much to distinguish itself in the golden age of Italian art will, in the upswing of Italian science, attain to a high place, who can say? With the modern tendency of universities and research laboratories toward the largest cities, the chances are perhaps against it

The physician traveling in Italy need not go to Venice to see universities and hospitals, but he will scarcely be able to resist visiting the city for its own sake And if he arrange to arrive there at night and the weather favor him, he will have memory traces the stamp of which he may hope to be indelible To step from the bustling railway station into a gondola, to lean back on the black leather seat, to glide through the quiet canals with the moon shining on the facades of the old palaces, to listen to the weird cries of the gondoliers' *a oel* or *sia stali* as they suddenly turn the corners of the narrow, twisting channels on the way to the hotel is an experience to treasure for a lifetime With the charm and mystery of St Mark's, the Palace of the Doges, the treasures of the Academy of Fine Arts and the School of San Rocco one can do without other medicine for awhile Almost by accident, however, one afternoon we wandered into the center of medical Venice Near the famous church of Santi Giovanni e Paolo, on the north side of the same square opposite the fine equestrian statue of Bartolommeo Colleoni, rises the rich facade of the Scuola di San Marco, dating back more than 400 years and known to every visitor of Venice on account of the singular reliefs (in perspective) of two lions On entering the building we found that it, together with the adjacent Dominican monastery, is used as a city hospital It is interesting to see how this fine old structure, with here and there a magnificent carved ceiling, has been transformed to the uses of an immense charity clinic The attendant who accompanied us, and busied himself to see that we missed none of the points of interest, finally led us to a human *Sehenswurdigkeit* It turned out to be something we had scarcely expected, a mere handful of man, curled up like a ball reputed to be 104 years old We spoke to him, but he was dull of sense and there was scarce noticeable reaction his eyes were motionless and dim, there was little left of him but skin, bones and a few gristly cords The scene recalled Stevenson's dying Paumotuan, "the human tragedy reduced to its bare elements a sight beyond pathos stirring a thrill of curiosity"

VI

FATHER DAMIEN THE LEPER HERO

NICHOLAS SENN, M D
CHICAGO

S S Sierra July 18

> Nothing is more delightful than the light of truth"—Cicero

There are heroes and heroines, men and women, who in times of danger do not hesitate to sacrifice their lives in attempts to save others Heroism consists in acts of unselfishness and courage of the highest type, under conditions of impending danger or calling for a degree of self sacrifice from which the average mortal instinctively shrinks Untimely death and self imposed deprivation of the comforts of life for the benefit of others who are in danger or distress exact from heroes the highest and noblest qualities of man—undaunted courage, unselfish charity and unconquerable love, and boundless humanity toward mankind Such a combination of the highest virtues is indeed rare, and when found entitles the hero to profound respect highest admiration and permanent gratitude of all nations and more especially the one benefited by his sacrifices The world looks to the battlefield as the arena for the exhibition of heroism in its truest grandest and noblest sense Military heroism has from time immemorial been immortalized in song and prose Heroism in war signifies courage and patriotism but lacks humanity and the greatest of all virtues charity The soldier knows that his bravery will be recognized and that in the event of his survival he may confidently expect that a grateful nation will reward him for his valiant services

Sudden, painless death in the heat and tumult of battle is in itself an honor a sufficient inducement for many to seek it when imbued with the justness of the cause for which they fight and stimulated by the fire of a burning patriotism Heroism in the cause of humanity, stripped of the excitement and glories of war, brings out the best attributes of man Heroism rendered at the altar of humanity, with no expectation of renown or reward among the sick and dying, under conditions attended by vastly more danger to life and health than the risks of war, gives testimony of the highest type of a hero or heroine

Such a hero was Father Damien the subject of this sketch During his life devoted to the welfare of exiled lepers, his motives were often misunderstood and his noble soul experienced many a pang when he was maligned as was not infrequently the case We can say of him

> "Glory comes too late when paid only to our ashes"—Martialis

Father Damien is no stranger to the medical profession (Fig 1) His heroic labors among the banished, maimed and disfigured lepers of Molokai, and his glorious death from the disease he fought so courageously, have made him a hero in the estimation of the medical profession and in the eyes of the entire world—a hero whose name will live long after the disease he fought and from which he died will have become extinct. As a humanitarian, his memory will go down to the future side by side with that of Henri Dumont as the leper hero, it will never die The whole life of Father Damien from the cradle to the grave was an exemplary one, and his work was characterized by unselfishness and an ardent devotion to his manifold and trying duties How it was possible that statements to the contrary could have been made during his lifetime is a mystery that admits only of one explanation—he, like other great men, had enemies whose envy was aroused by the marvelous success in everything he attempted His entire career as a priest and friend of the lepers breathes a spirit of true earnest Christianity which those who knew him best never questioned The malicious attacks on his character were made by men who were too cowardly to visit the leper settlement and observe his work among the thousand unfortunates whose pains he soothed and to whose spiritual needs he ministered with an unparalleled zeal and untiring devotion, whose dying he consoled, and whose dead he buried in coffins and graves often made by his own hands As a true minister of the gospel, he served his God and leprous congregation with a devotion and faithfulness that knew no limits, by day and night, in sunshine and storm

Father Damien's name in the world was Joseph de Veuster, He was born at Tremelo, near Louvain, Belgium, Jan 3, 1840 His parents were honest, hard working, devout peasants who raised a family of seven children, four of whom entered the service of the church—his older brother, Pamphile, and two sisters The earliest desire of his boyhood was to become a priest, in which vocation his older brother preceded him The parents being poor, he struggled with the greatest difficulties to realize his desire He finally entered the College of the Fathers of the Sacred Hearts of Jesus and Mary, and entered holy orders at the age of 19 The splendid health which he enjoyed throughout his long student life was gained during his boyhood days, spent in hard work on the farm The cloister life made him abstemious, and exhibited an irresistible attraction for the rigors of austere penance Early piety and a tender affection for his parents, as shown in all his letters, laid the foundation for a successful priestly career When he entered the cloister he was the very embodiment of health, strength and activity Endowed with great mental power and applying himself closely to his studies, his progress was rapid, and when he left the institution he was well prepared for his chosen life work Although serious, he was not ascetic In a letter to his parents during his theological studies, in commenting on the uncertainty of life, he says "The thought of the uncertainty of to-morrow must, no doubt, cause bitter grief to a sinful soul, but for us, Christians or religious, who look on ourselves as exiles here below, and who long only for dissolution of our body that we may enter our true country, there is, it appears to me, only joy and blessedness in the thought that each moment we get nearer to the last hours of our life" His splendid health, his love for an abstemious life and es

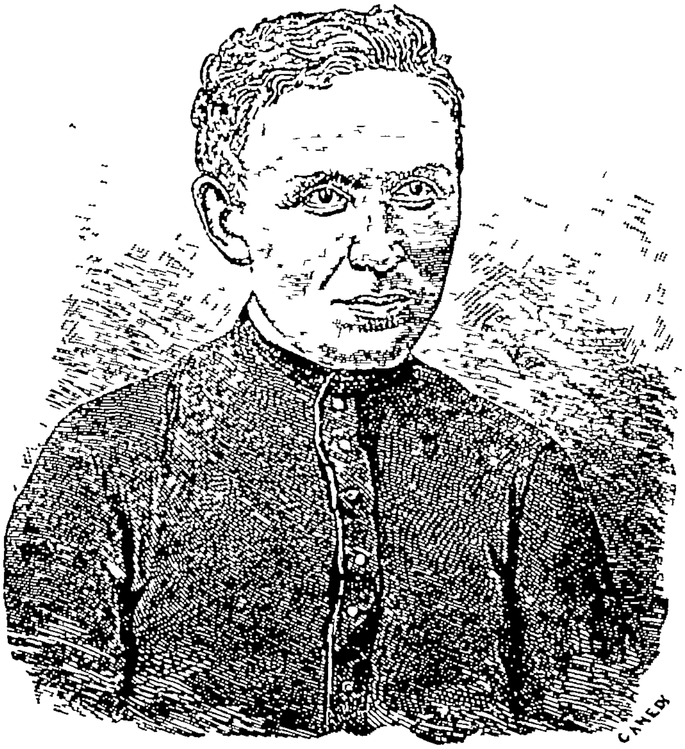

Fig 1 —Fr Damien de Veuster at 33 years of age when starting for the leper settlement

was very fortunate, indeed, that Father Damien contracted the macular instead of the tubercular form of the disease, and that the palmer side of fingers and hands remained clean, permitting him to perform his spiritual functions until a few days before his death, which occurred April 15, 1889

So ended the precious life of one of the greatest benefactors of the human race—the hero of charity! The greatest heroism of Father Damien was exhibited during his illness, as he persisted in working with hands and heart until a few days before his death What could touch the human heart more than to see a leper priest render manual work and spiritual consolation to a congregation of lepers, the blind leading the blind, the lame supporting the lame! His heroic death has silenced the vile tongues The surviving lepers can not be comforted, they will carry their grief over the loss of their faithful shepherd to their graves The entire population of the Hawaiian Islands—in fact, the whole world—mourns his death He has gone to his well earned reward His mangled remains sleep under the shadows of the pandanus tree which first sheltered the robust, devoted young priest awaiting a glorious resurrection (Fig 3)

Volumes have been written in praise of Father Damien Monuments have been erected to his memory, charitable institutions have sprung up to immortalize his heroic charity but if that humble priest could speak to his admirers he would say "I have only done my duty, praise God Send greetings and extend a helping hand to my leper friends"

Clinical Notes.

A CASE OF CARBOLIC ACID GANGRENE

E DUNSTER KREMERS, M D

HOLLAND, MICH

Introduction—I am able to report this case through the kindness of Dr A Leenhouts, under whose care I saw the patient This report is added to an already long list of cases, not because of its rarity or its unusual features, but because some physicians are still unaware of the danger in using carbolic acid as a dressing and in the hope that through their physicians' knowledge the laity may understand how to avoid the needless destruction of fingers and toes by this poison

History—G H R, age 15, male, schoolboy The patient has always been a strong, healthy boy On July 4, 1904, he was washing dishes and cut the little finger of the right hand by a piece of glass There had been a case of tetanus in the town and, on the following morning the boy's sister fearful of "blood poisoning," applied a rag soaked in carbolic acid solution She had been using a solution as a wash on an infected arm and had seen no ill effect The solution was made weak in the proportion of about three drops of the liquefied acid to fifty drops of water Twenty four hours later this rag was removed and the skin of the finger "looked funny" The patient thought that the antiseptic was failing in its work and accordingly a stronger solution was made and the bandage bound very tightly The next morning the finger was "all white" and was massaged

Treatment—July 8 Dr Leenhouts was consulted and applied a wash of boracic acid, hoping to restore the circulation July 11 the finger became black and began to be tender and July 13 the patient went to bed feeling badly and with evident fever At this time the finger was entirely bluish black with a well marked line of demarcation about one half inch below the metacarpo phalangeal joint Above this there was a line of redness and swelling

Operation—Under chloroform anesthesia the finger was amputated at the metacarpo-phalangeal articulation No pus was found a healthy flap was secured and united by silk sutures July 14 the temperature rose to 103 degrees at evening was 101 and the following day normal There was no further trouble and the wound healed by first intention Urine examination was negative

Comments—The strength of solution used in this case was probably about 5 per cent, because water will take up only that much It was applied for about forty eight hours and caused the patient no pain or discomfort The tight constriction of the finger undoubtedly assisted in the production of complete gangrene, but probably the first application would have been sufficient

TREATMENT AND ETIOLOGY OF PNEUMONIA

W J GALBRAITH, A M, M D

CANANEA, SONORA, MEXICO

Including those cases mentioned in my article, published in THE JOURNAL, July 9, 1904, I have had up to date, July 30, thirty seven successive recoveries of uncomplicated cases of pneumonia which were treated according to that article My experience during the season just passed covers over two hundred cases, and careful observations lead me to believe there is a factor preceding the active physical signs of pneumonia which, by careful examination, can be detected in many cases prior to the stage of engorgement

Unfortunately, it is impossible to get a positive history as the anesthetic properties of alcohol are a mask for reliable record However, in those cases that have come under my care at an early date I have frequently been able to detect tenderness, from a mild to a severe degree, in the region of the gall bladder, with a corresponding amount of pain in the same region which may extend to the left and upper lobes of the liver The tenderness and pain are invariably relieved as soon as the physical signs of pneumonia develop Those cases that are preceded by severe gall bladder pain and bilious vomiting, I have invariably noticed, are followed by troublesome tympanites

Just what relation, if any, these preliminary symptoms have to pneumonia I am unable to state at the present time I would not be surprised if time would prove that microbic invasion of the gall bladder may become an etiologic factor in pneumonia If any practical knowledge can be demonstrated from these theoretical views we have accomplished all that theory is entitled to

GONORRHEAL INFLAMMATION OF STERNO-CLAVICULAR ARTICULATION

IN ONE CASE COMPLICATING FRACTURE OF CLAVICLE

R L LARSON, M D

CHICAGO

CASE 1—John S, aged 20, came to me a few weeks ago with the following history

History—Three days previous he fell off a horse's back, striking on his left shoulder, apparently receiving only a slight contusion of the soft parts around the shoulder girdle He paid no attention to it until great soreness and tumefaction ensued

Examination—I found well marked evidences of simple, oblique fracture of the clavicle at its middle point At the junction of the middle and inner thirds there was a hard, bony swelling, which he stated was the result of a fracture about a year ago, for which he was treated at the Alexian Brothers' Hospital There was good union at this point

I noticed a prominent swelling at the sternal articulation of the clavicle, which I did not think was concomitant with the recent fracture The patient stated that he had an uncured urethritis of some three weeks' standing, and that this sternal swelling had appeared some three days previous to the accident It was very painful and he was unable to use his arm to any great extent The recent accident only spurred him on to see a physician

Examination of the urethral discharge distinctly demonstrated the presence of gonococci

Treatment—Along with the surgical treatment of the fracture I administered the necessary treatment for his gonorrheal urethritis With three inch width strips of adhesive plaster I applied a Velpeau bandage, and maintained the upper extremity and clavicle in good position

Results—Within four or five days the sternal swelling disappeared and in twelve days the urethritis vanished, and then there only remained the subsequent treatment of the clavicle At the end of the fourth week the patient wished to return to work as barn hostler and I very reluctantly freed him from his bonds I had contemplated having him tied up for at least six weeks, considering the injury of a year before and his recent complication

Now that five or six weeks have elapsed, I had the opportunity to examine this young man, and I find excellent motion in all the joints concerned

CASE 2—A case of interest in this connection occurred about two years ago

History—A young man, aged 21 years came into the hospital during my service with a prominent swelling of the sterno-clavicular articulation The chief surgeon suggested immediate removal of the sternal end of the clavicle His diagnosis was "rapidly growing osteosarcoma" of the clavicle

Now the boy gave a distinct history of an uncured gonorrheal urethritis for the past two weeks Microscopic examination showed gonococci An *x* ray picture showed slight shadow of circumscribed swelling at sterno clavicular junction The 'tumor" had steadily grown for the past week I argued in favor of gonorrheal synovitis

Treatment—Despite an interne s hopes and suggestions the boy was placed on the operating table next morning and everything made ready for operation When I removed the antiseptic compresses from the region of the neck and chest the swelling was found reduced at least 60 per cent. of its original size on the day previous It originally was larger than a hen's egg, well defined, around and posterior to sterno-clavicular articulation No operation was performed outside of manipulation from the hands of the curious

Suggestions were offered that the use of the *x* rays had occasioned this wonderful change and they were used daily for ten days The patient then left the hospital he and his friends holding the vague idea and opinion of a surgeon s skill in the use of the *x* rays and magnetic touch

63 East Chicago Avenue

A CASE OF TETANUS TREATED BY SUBDURAL AND INTRASPINAL INJECTIONS OF ANTITOXIN DEATH

C W WILLE, M D
Assistant Surgeon Public Health and Marine Hospital Service
BALTIMORE

Introduction—The interesting phenomena which happened during the progress and treatment of a case of tetanus which occurred recently in my service[1] impels me to place the notes of the case on record I believe the interests of the profession are best served by collating the material from all cases, whether successful or not

History—A male negro, 24 years of age, was admitted to the U S Marine Hospital, Baltimore, at 4 p m, June 16, 1904 He complained of stiffness of the muscles of the lumbar spine, with rigidity of the muscles of the back of the neck He noticed the beginning stiffness eighteen hours previous to admission to hospital, and ascribed his condition to the free drinking of ice water throughout the day

Examination—On admission he had considerable rigidity of the muscles of the lumbar spine and of the back of the neck The neck was arched backward and there was slight opisthotonos The jaw was stiff so that the mouth could not be opened as widely as formerly On inquiry, the patient admitted that while working about a stable he ran a nail into the sole of the right foot just five days prior to the onset of his symptoms He stated that the wound gave him no further trouble.

Later Symptoms—Two hours after admission there was noticed a decided increase of the rigidity of the muscles of the back, with some beginning stiffness of the muscles of the abdomen and flexors of the left thigh The patient was sweating profusely, especially over the upper portion of the chest, neck and face His skin was cool, temperature, 36 6 C, pulse, 55 beats to the minute, full and strong Heart action was tumultuous, no murmurs There was now some difficulty in swallowing, and beginning stiffness of the sternomastoid muscles

Three hours after admission there had developed, in addition to the tonic contractures mentioned above, an intermittent clonic spasm affecting especially the lumbar spinal and abdominal groups of muscles These spasms arched the patient considerably They were not typical of tetanic convulsions, being shorter in duration and occurring with greater frequency The patient had an unnatural wrinkling of the skin of the forehead, due to the involvement of the occipitofrontalis muscle There was no involvement of the risorius muscles The muscles of the chest—that is, the intercostals, the pectoral and serratus magnus muscles—were only slightly rigid, and there was no embarrassment of respiration The urine was normal, and there were involuntary evacuations of the bowels All mental faculties were preserved, and there did not appear to be any hypersensitiveness to outside influences

Treatment and Result—Chloral was pushed in gram doses at half hourly intervals during the six hours following admission It produced drowsiness, but failed to have any effect on the spasms Under chloroform, seventeen hours after admission, the skull was trephined over the parietal eminence, and 20 c c. tetanus antitoxin were slowly injected under the dura The wound was closed without replacement of the button of bone At this time, 5 c.c of cerebrospinal fluid were withdrawn in the ordinary antitoxin syringe by lumbar puncture, followed by the slow introduction of 10 c.c antitoxin into the spinal canal This latter procedure was thought advisable in order to get the more immediate effect on the toxin locked ganglion cells which control the involved spastic abdominal and spinal muscles The wound of entrance was laid open and packed There was no shock incident to the operation, the patient reacted rapidly, and for three hours was free of spasms As the effects of the anesthetic wore away, the convulsive movements returned, the patient dying of asphyxia within five hours after operation

Remarks—The points of interest to be noted in this case are the short period of incubation which was exactly five days, the extreme rapidity of the course of the disease—forty two hours—the marked involvement and apparent selection of the lumbar spinal and abdominal groups of muscles, and the comparative freedom from involvement of the muscles of the limb through which the tetanus organisms and toxin made their entrance The negative evidence deduced from this case would advise, I believe, an early recourse to the use of antitoxin administered subcutaneously or along the sheath of the nerve trunk supplying the injured location as a preventive measure, or subdurally or intraspinally as a curative procedure

---

Diphtheria in Healthy Throats—M Geirsvold of Christiania states in *Tidsskrift f d Norske Laegeforen*, No 23, 1903, that he found diphtheria bacilli in the throats of 9 2 per cent of 967 presumably healthy school children examined The investigations were conducted in the schools during the period from May 28 to June 20, and 87 children were found to shelter the bacilli, in pure cultures in 22 In a later series in the fall he found them in 3 4 per cent of 178 children. None exhibited any clinical symptoms He remarked that this proportion is probably below the actual number, and that the children too young to go to school and adults also probably show a similar proportion, consequently strict isolation on the bacteriologic findings is impracticable

RESPONSIBILITY AND CRIME

It was left to President Roosevelt, in a recent memorandum, clearly to enunciate a characteristic, common-sense view of the plea of insanity in extenuation of crime. He said:

> I have scant sympathy with the plea of insanity advanced to save a man from the consequences of crime, when, unless the crime had been committed, it would have been impossible to persuade a responsible authority to commit him to an asylum as insane. Among the most dangerous criminals, and especially among those prone to commit this particular kind of offense [rape], there are plenty of a temper so fiendish or so brutal as to be incompatible with any other than a brutish order of intelligence, but these men are nevertheless responsible for their acts, and nothing more tends to encourage crime among such men than the belief that through the plea of insanity or any other method it is possible for them to escape paying the just penalty of their crimes.

With this view we know some of our psychiatric friends will take exception. Much has been said and written that appeals to our sympathy with a view to preventing the insane criminal from suffering the regular penalty of the law. In some specific instances this plea has been urged with such publicity and under such unwarranted circumstances as to have brought much obloquy on scientific psychiatry. It has become a popular by-word that such and such a criminal will "play the insanity dodge" and escape the punishment due him.

In this direction we have gone too far. Sentiment and metaphysics on a substratum of scientific truth have woven a structure of words that has for a time overwhelmed our common sense. The President does us a service in so graphically striking to the root of the matter. To the general physician it seems the time has come to take a less assailable position on this question of responsibility in crime. The following propositions, then, seem to afford a nucleus for such a common-sense view:

> 1. A person under trial for crime, if not sufficiently insane to require isolation in an asylum, should be held legally and fully responsible for all his acts. The plea that he became suddenly insane at the time of committing his criminal act, while scientifically true in many cases, should not be permitted to secure him immunity from punishment.
>
> 2. Either he should be judged exactly as would be a sane and mentally responsible criminal, or else, under laws most urgently needed, he should be committed to an asylum especially equipped for such cases for the remainder of his life, on the ground—well sustained by many tragedies—that it is not possible to predict when he will again be seized by an insanely criminal impulse.

At present it is too easy for "influence" to release from the asylum the criminal who has been adjudged "insane." There is little doubt that the adoption of these propositions would, like magic, reduce the proportion of criminals who plead insanity as an excuse for crime.

As a matter of fact, while supported by the scientific arguments of respected psychiatrists, the "insanity plea" is chiefly used by shrewd but not too scrupulous criminal lawyers to extricate undeserving criminals from well-earned punishment. The alternative of life commitment to an asylum renders certain the escape from punishment of every really insane criminal. The time has come, we believe, for the organized profession to ask legislatures to amend the criminal laws along the line suggested. It is certain that this course will insure to the profession a large share of public approval.

THE PRODUCTION OF ANTITOXIN BY AUTOLYSIS

The discovery of the remarkable property of the animal body to produce antitoxins in response to the injection of toxins has opened up an entirely new field of investigation in physiology. Very extensive experiments have been carried out by a large number of investigators in the hope of discovering the mechanism and the exact location of the production of these antibodies, but very little is as yet definitely known. Several theories have also been advanced to explain this process, but none of them is entirely satisfactory. It has been shown, for instance, that antiabrin and cholera immune bodies are present in the spleen and in the bone marrow of an animal, in the process of immunization, before they can be found in any other part of the body. It has also been shown that an emulsion of brain tissue has antitetanic properties, and substances having antitetanic properties have been isolated from normal spleens and adrenal bodies. These facts seem to speak in favor of the view that antitoxins are produced in a limited number of organs, and perhaps in different organs according to the nature of the toxin injected.

In consideration of the facts that antibodies are, with very few exceptions, specific substances, and that they appear only as a result of the injection of toxins, it has been held by Buchner, Metchnikoff and others that they result from the transformation of toxins by the organ cells. According to this theory, they are not produced from substances that are normally found in the body, but from substances that are injected with the toxin. According to Ehrlich's side-chain theory, on the other hand, antibodies are nothing more than receptors of the normal cells, which are produced in excess and given off to the blood in consequence of repeated injections of small doses of toxins.

Although these two theories are very different from one another they both suppose that the production of antitoxins calls forth an increased activity of the tissue cells Blum[1] has now raised the question whether antibodies could not be produced by an increased breaking down of the tissue cells in consequence of the injection of toxin instead of being the result of an increased and special activity This breaking down of tissues would lead to autolysis of the dead cells, which might give rise to substances having protective properties against the toxin that has been injected In favor of this view he points out that the injection of toxin during the process of immunization is followed by fever, leucocytosis and loss of weight He also carried out a number of experiments in which he showed that tetanus antitoxin is produced by the aseptic autolysis of animal lymph glands *in vitro*

Beef lymph glands were collected under aseptic precautions, chopped fine and mixed with toluol, and then covered with twice their weight of physiologic salt solution and placed in the incubator for one to seven months Half a c c of the liquid of some of these mixtures protected white mice against ten times the minimum fatal dose of tetanus toxin

The antitoxin contained in these fluids is largely retained in a porcelain filter when the fluid is filtered It can be precipitated with ammonium sulphate, and in other respects behaves like the antitoxin in immune serum It can not be said, however, that the antitoxin produced by autolysis of lymph glands is identical with that produced in the animal body by the injection of toxin, but the fact that the two behave very similarly toward various chemicals (ammonium sulphate, acids, alkalies) suggest this possibility

THE PHYSICIAN HIMSELF

The recent wide spread of the cult for Dante and the study of details relating to his life and position in Florence have brought out some facts that can not fail to be of extreme interest to physicians Dante, as is now well known, was a member of the Guild of Physicians and Apothecaries in Florence This does not mean necessarily that the great poet knew anything either of medicine or of pharmacy As has been recently called to renewed attention by Julia Cartwright in her book, "The Painters of Florence," "by the laws of Florence painters and sculptors belonged to the Guild of Physicians and Apothecaries, which was one of the seven major or higher class of trades, and each artist was required to matriculate in this body before he could practice as an independent artist" She adds "This close connection between painting and medicine dates back to very early days, and receives further illustration from the fact that St Luke was the patron of both doctors and artists"

Very few communities have realized the true relationship of art and literature and the well-being and proper educational development of their citizens, as did the Florentines of the times just before and after Dante This placing of the artists and literary men then, in the Guild of Physicians and Apothecaries is something much more than mere chance, or some fortuitous necessity of municipal distribution of civic influence These people of the early Renaissance, at a time when probably artistic ideals were closer to the heart of the generality of the people than has ever been the case since, felt that the physician by his profession should be a leader of those whose influence makes for the uplifting of life Something there was evidently of the idea, too, that his presence and his power of suggestion must be able to raise people above themselves and the physical ills to which they were liable, as the artist and the literary man accomplish similar purposes for those in health

There is surely in this story of the old medieval town and its principal guild, that of the physicians and apothecaries, a lesson that the modern profession may well take to heart, for it serves to show, first how broad must be the interest of the physician in everything that relates to the esthetic side of life if he would not fail of the high aims of the brotherhood, and second, how closely he must feel his fellowship with the artist and the literary man himself, how much he must cultivate the higher things of life and art and letters in order to occupy that position with regard to his patients that is properly his The idea may seem far-fetched to a practical generation, but it is by such an ideal that the physician will secure not only success, which is not the sole aim in life, but also that supreme satisfaction which comes from ever-increasing self-development, and that exercise of faculties which constitutes the only real happiness of life

CO EDUCATION AND RACE SUICIDE.

Co-education in the higher institutions in this country is still on trial, at least if we can judge by the variances of published opinions Of late the utterances against it have been rather more prominent and positive It has been alleged also that the higher education unfits women physically for the duties of motherhood and that, much against their will in many cases, they remain childless or comparatively unfertile, or suffer excessively in fulfilling the functions of reproduction after marriage The question of co-education as a factor in race suicide, so called, which is at present somewhat engrossing the public mind, has been raised Dr G Stanley Hall, whose extensive studies of adolescence, as well as his experience as an educator, render his opinions worthy of serious consideration, claims that the effect of co-education is bad, that it de-feminizes the female and feminizes the male, and generally interferes with the laws of nature so as to reduce the ratio of both marriage and offspring On the other hand, experienced educators like President Angell of Michigan University see only good in co-education or at least a vast preponderance of good over evil

---

[1] Hofmeister's Beitrage 1904 v, 142

Leaving aside the purely social aspects of the subject as not capable of being fully discussed here, there still remains several points of medical interest. It is difficult to obtain definite, trustworthy statistics of the frequency or infrequency of marriage and of the fecundity of college-bred women, but one thing may be admitted as probable, that the ratio of marriages is somewhat less among female graduates of the higher institutions than among the female population generally. A woman's chance of marriage rapidly diminishes with age, and the completion of a full college course leaves the female graduate at a period of life with appreciably diminished marriage expectancy. Moreover, married women who wish to devote themselves to the higher studies probably think less of marriage as an object in life than do others and this also may affect the statistics. A rather extensive study of alumni records would be required to afford a basis for conclusions, and we doubt if this has been made. As far as the effects of co-education are concerned moreover, a comparison is needed of the data from exclusively female institutions like Vassar, Bryn Mawr, Wellesley and others with those of co-educational schools, and it is possible that the result might be favorable to the latter. The claim made by President Angell that co-education affords special advantages for the selection of lifemates is also to be considered. In looking over the alumni records from one large co-educational institution and taking into account those graduates only who may reasonably be inferred to have completed the reproductive period, the average number of children was about four, where any data were given. The corresponding study of one exclusively female institution gave a lesser figure. If Dr. Hall's assertion is a statement of a rule, the exceptions are altogether too numerous to prove it.

Still another point needs mentioning. It is quite possible the concentration required by the higher studies may often have a deleterious effect on the proper development of the adolescent female. This is a rather serious matter. Girls are often more ambitious in their studies than boys, and therefore more liable to receive damage from this cause, and it may be that the competition between the sexes in co-educational schools may aggravate this possibility. The subject taken altogether is an important one, and careful research, if it is possible, as to the physical effects of the higher education in women is desirable. Apart, however, from the general effect of the higher education on the female organism the influence of co-education by itself as a factor in producing physical race degeneration is not yet satisfactorily proved.

NEO MALTHUSIANISM IN AUSTRALIA

Neo-Malthusianism seems to be a popular theory in Great Britain's southern dependances of Australia and New Zealand. According to recent statistics, the birthrate has fallen in Australia to a figure far below that known in any other country and one that leaves little margin, if any, for the increase of population. In 1893 the ratio was 19.17 per 1,000, while ten years later, in 1903, it was only 14.90 per 1,000. It is thought certain that the decline is still continuing, and at this rate it will not be so very long before the problem of a diminishing population will have to be met. Australia is not a crowded continent, there is abundant room for a larger population even with the unfavorable climatic conditions that exist over a large part of its territory, but, like New Zealand, which is following in the same path, it is a country of social experiments. Immigration has been practically checked by labor laws, etc., and present conditions do not favor its revival. With lessening population and a public debt, the greatest of that of any community, some $278 per capita, a ratio which is not likely to be decreased according to present appearances, England's southern empire would not appear to be in a very good way. Social experiments evidently come high and the experience of Australia is not encouraging. Population, as Mr. Kidd truly says in his "Social Evolution," is the rock on which all socialistic systems split, but this apparent attempt on so large a scale to meet the problem in Australia and New Zealand is likely to place them at the very top, or perhaps we should say at the bottom, of the list of decadent populations. The star of empire appears to be waning somewhat over England's southern dependencies.

HEMORRHAGE INTO THE ADRENAL GLANDS IN INFANCY

Although little is known concerning the function of the adrenal glands, and scarcely more with regard to disease of these organs, there is reason to believe that they fulfill a not unimportant purpose in the economy, probably through the generation of an internal secretion. Whether this latter is effective directly, through the agency of its vasoconstricting principle, or indirectly, by neutralizing substances circulating in the blood, is not yet known, but that it is in some way profoundly concerned in the body-metabolism is clearly shown by the results of destruction of the adrenals either by disease or by experimental means. The effects of partial lesions of the glands are not obvious, perhaps because even a small residuum is capable of supplying sufficient secretion for the needs of the organism. Hemorrhage into the adrenal glands has not rarely been observed in still-born children, and less commonly in early infancy. In some instances, especially of the first group, it is probably due to mechanical conditions attending parturition, while in others, particularly of the second group, the underlying cause is some infectious process, although this may not always be obvious. In the latter, acute abdominal pain and vomiting set in suddenly in a child previously in apparent health, and the temperature becomes elevated above the normal. A purpuric eruption sometimes appears, and there may be hemorrhages from mucous membranes. Convulsions supervene, and death takes place in the course of a few hours. Three cases of this character, one occurring in a male infant three days old, one in a boy two months old, and the third in a girl seven months old, are placed on record by Mr. Frederick

Langmead,[1] who notes the resemblance of symptoms to those attending acute specific diseases of malignant type.

PORTAL THROMBOSIS WITH HEMORRHAGIC INFARCTION AND NECROSIS OF THE LIVER.

Acute thrombosis of the portal vein is characterized clinically by the occurrence of severe abdominal pain and copious hypostatic hemorrhage from the organs whose vessels unite to form the portal vein. When such acute obstruction is complete, death results rapidly from loss of blood; but if the obstruction is only partial, ascites, enlargement of the spleen and recurrent hemorrhage develop. The condition is usually dependent on disease of the walls of the portal vein, and this may be associated with other morbid states of the liver or in the vicinity of the portal vein. The most important etiologic factor in this connection is syphilis, involving either the liver or the vein itself. Among other causative influences are cicatricial processes in the transverse fissure secondary to chronic peritonitis, compression by tumors, enlarged glands or gallstones, atheroma and sclerosis. Acute thrombosis of the portal vein does not give rise to any considerable alterations in the liver, because the hepatic artery still suffices to maintain the nutrition of that organ. When, however, emboli are carried into the branches of the portal vein, a condition results that has been designated atrophic red infarction. In order that this may occur, there must be interference with the supply of arterial blood to the liver, together with disturbance in the venous circulation of the body. There is another form of infarction of the liver, namely, the anemic-necrotic, which may be attended with true hemorrhage into the liver tissue. It is a condition secondary to thrombosis, and it is dependent on obstruction of the circulation in the hepatic artery. An unusual case of this character has recently been reported by Dr. F. Steinhaus.[2] This was an instance of mixed autochthonous and traumatic portal thrombosis, with secondary alterations in the liver in the form of extensive necroses and true hemorrhagic infarction, developing in a coachman who had been kicked in the right hypochondrium by a horse. The changes in the liver are attributed to complete connective tissue obliteration of the interlobular branches of the portal vein, which was probably the seat of a primary circumscribed endophlebitis, causing extensive alterations in the smaller and smallest branches and necrosis of the liver tissue before the injury, as extensive cirrhotic changes with excessive proliferation of biliary passages seemed to indicate that the entire process had existed for some time. The blow in the right hypochondrium, it is reasoned, gave rise to acute necrosis of the fatty tissue of the pancreas, and fresh thrombosis of the right suprarenal vein, with hemorrhage into and necrosis of the adrenal body, as well as fresh thrombosis of the larger branches of the portal vein. The case must be looked on as an evidence of the etiologic significance of traumatism with relation to acute necrosis of the fatty tissue of the pancreas, as well as to thrombosis of the portal vein.

SURGICAL SCARLATINA.

Since Sir James Paget, in 1864, presented a clinical lecture on the subject of scarlet fever as a sequel of operations, the possibility of such an occurrence has been generally recognized, and frequently discussed, diagnosed and reported. Numerous epidemics in hospitals have been recorded, besides isolated cases, as well as experimental inoculations. It has become evident to all, however, that in the earlier days particularly much confusion has existed between true scarlet fever and scarlatiniform rashes, such as may result from septic infection or from drug intoxications, particularly carbolic acid. Still there are undoubtedly instances of true scarlet fever following shortly after an operation. The possible explanations suggested have been that in surgical scarlet fever we have to do with a wound infection by the unknown virus of scarlet fever, or that the resistance of the body is lowered by the operation so that a latent infection with scarlet fever is enabled to develop, or that the recorded cases are merely the outcome of coincidence, favored perhaps by the great exposure of hospital patients to contagious diseases. It is apparent that the exact status of surgical scarlatina is a matter of great importance from the standpoint of the searcher for the etiology of scarlet fever, for if it can be shown that the infectious agent is such that it is likely to enter an operation wound we would be able to add considerably to our scanty store of information on this subject. The relation of streptococci, which are so important as factors in the mortality of scarlet fever, and so frequently found in the disease that not a few have considered them the specific cause, is raised prominently by the known tendency of streptococcus infections in wounds to lead to not only local but general erythematous eruptions. Indeed, some writers have considered this close analogy of scarlet fever as seen after operations with other better known infections, to indicate that the same infectious agent may in one person cause erysipelas, in another puerperal fever, phlegmon, lymphangitis or scarlet fever. Dr. Alice Hamilton,[1] reporting a series of ten cases of a condition such as is described in the literature as surgical scarlatina, considers the questions: Is this disease really scarlatina, and if so, what is the relation between the injury and the disease? The possibility that ordinary septic infections, erysipelas, etc., can have the same cause as scarlet fever, would seem to be ruled out by the fact that the latter is followed by an immunity, while the former is not; and also, we might add, that immunity to scarlet fever does not protect in any way against ordinary streptococcus infections. Analysis of the 174 cases of surgical scarlatina that have been reported led to the view that in many of the cases what had been reported was really septic infection with eruption, and not scarlatina. This is probably the explanation of the belief that surgical scarlatina differs from the ordinary form in having a shorter incubation, little or no angina, a rather early desquamation, and the onset of the eruption in the wound or some other unusual region. There seems to be no convincing proof that there is a special form of "surgical scarlatina," but rather that the *bona fide* instances of scarlet fever in the wounded have been merely coincidences, and *not* that the wound serves as an infection atrium for the disease

THE LYMPH GLAND METASTASES IN CARCINOMA OF THE STOMACH

The question of the situation and appearance of the lymph gland metastases in carcinoma of the stomach is of both medical and surgical import From the medical standpoint it is important to know how frequently and how early we may expect metastases at a distance which might be of aid in the diagnosis of the condition, particularly as certain French observers have laid some stress on enlarged clavicular glands in this connection From the surgical standpoint the matter is of much greater importance, as a knowledge of the lymph-gland distribution of stomach carcinoma is absolutely essential if the surgeon is to know how much tissue is to be removed with the affected portion of the stomach in order that there may be no recurrences

Up to the present the most important work on this subject has been contributed by Cuneo, but this author confined his studies to the glands in the immediate neighborhood of the stomach, and did not study those at a distance Quite recently, Renner[1] has tried to fill the gap in our knowledge in this direction This author attempts to answer several important questions, namely, whether a macroscopic test is sufficient to distinguish a cancerous from a non-cancerous gland, whether there is a definite relation between the seat of the tumor and the group of glands affected, whether the secondary growths are due to direct extension or metastasis, and whether in operative cases, which subsequently come to autopsy, infected glands can still be demonstrated The first query the author answers very decidedly in the negative, he shows that while on the one hand glands which appear to be enlarged contain no carcinoma, on the other very small and apparently non-implicated glands may be full of new growth He therefore advises the removal of all glands in the neighborhood of the operative field As far as a correspondence between the situation of the growth and certain groups of glands is concerned, the author shows that this exists to a certain extent, thus in fifteen cases the glands draining the seat of operation were carcinomatous, while in four cases they were not The evidence of transmission of the growth was practically all in favor of transmission by metastasis, as only in rare cases was there any sign that direct transmission had taken place The study of operative cases at autopsy showed that in fifty per cent of the cases there was no regional glandular recurrence

The general result of the study was to show that the glands of the lesser curvature are those most frequently infected, next the suprapancreatic, and then the subpyloric In the limited number of cases investigated there was no case showing metastases to the clavicular or cervical glands, so that enlargement of these glands is probably of little diagnostic value and occurs so late that operative interference at the time of its discovery would be out of the question

Medical News.

COLORADO

Academy Will Build—The Denver Academy of Medicine will erect a two story and basement building, at a cost of $20,000 to be used exclusively for physicians

Sisters Buy Sanatorium—The Sisters of Mercy of Maniton have purchased the Montcalm Sanatorium in that city and will remodel the building and equip it as a hospital at an expense of about $5,000

July Deaths—During July 769 deaths and 32 stillbirths were reported in the state, equivalent to an annual death rate of 15 65 per 1,000 One death was due to scarlet fever, 6 were caused by diphtheria, and 19 by typhoid fever

Health Appointments—Health Commissioner Dr William H Sharpley, Denver, has appointed Dr J W Jordan, county physician, Dr J William Dillon, assistant county physician Dr William C Mitchell, bacteriologist, and Dr Frank R Coffman, medical inspector

Contagious Diseases—The State Board of Health reports that during July 126 cases of typhoid fever were reported, an increase of 95 over June, 64 cases of diphtheria, an increase of 5, 64 cases of smallpox, an increase of 25, and 52 cases of scarlet fever, an increase of 7

Consumptives Are Being Cured—The Jewish National Hospital Association for Consumptives, of Denver, at its annual meeting reported that up to the beginning of the year 169 patients had been admitted to the hospital, of whom 4 had died, and 151 had been discharged cured, but of course these "cured' patients are obliged to remain in the Rocky Mountain zone

GEORGIA

Physician Loses by Fire—The house of Dr James I Wilson was destroyed by fire, July 11 The loss was $7,000, insurance $5,500

New Hospital Opened—The new King's Daughters' Hospital Atlanta, erected at a cost of $12 000, was formally opened July 18

Lengthened Course Deferred.—The senate acted on the amendment to the medical bill requiring medical students to attend four full terms in full separate years, after considerable discussion The vote stood 16 to 16, and the matter, on motion, was tabled

Personal—Dr and Mrs W Simpson Elkin, Atlanta, have returned from Europe——Dr William D Jennings, Jr, has succeeded Dr Ernest C Morris as city physician of Augusta——Dr Joseph H. Redding, Waycross, was seriously injured in a runaway, August 12

Tuberculosis Bill Passed—Senator Jordan's bill providing for a tuberculosis commission composed of one member from each congressional district and ten members at large, to investigate consumption in the state and make reports on progress at stated intervals, has passed the senate

ILLINOIS

Smallpox at East St Louis—On August 19, Dr Elvin F Baker, Jacksonville, inspector of the State Board of Health, reported that there had been 68 cases of smallpox, with 8 deaths, in East St Louis, during July

Personal.—Dr Ed P Sloan, Danvers, has returned from Europe and located in Bloomington——Dr James W Morgan, Moline, has sold his practice to Dr James M Wood, Kewanee, and will retire from active work——Dr Daniel W Young, Paris, was seriously injured by a fall on an iron picket fence August 8

State Board Establishes Laboratory—The State Board of Health has secured quarters in Springfield for a laboratory, which is being equipped with the chemic and biologic apparatus necessary to the work of the board, with especial reference to water examinations, the prevention of communicable diseases, and the search in the campaign against tuberculosis

Chicago

Granted New Trial—Dr Anna Beatrice Schultz, who was convicted and sentenced to an indeterminate term in the penitentiary for alleged implication in diamond robberies in Pittsburg and Chicago, has been granted a new trial by the Supreme Court and has been released under heavy bond

---

[1] Mittheilungen aus den Grenzgebieten der Medizin und Chirurgie vol xiii No 2, 1904

Personal—Dr Alfred C Croftan has been appointed physician in chief to St Mary's Hospital and Dr A J Ochsner, surgeon in chief——Dr Frank Billings has returned from Mackinac——Dr and Mrs Frank L Mueller were seriously injured in a collision between their trap and a Lincoln Avenue car, August 15 Dr Mueller suffered a fracture of the left clavicle and scapula and Mrs Mueller was internally injured——Dr Norman D Curry has returned from Europe

Rauch Park.—The obituary notice of Dr John H Rauch, which appeared in The Journal of March 31 1894 contained the following paragraph The public park system of Chicago, the water supply, the drainage canal of the city and a multitude of public works recommended by him will perpetually remind the coming medical historian that in this age lived a wonderfully energetic and capable sanitarian' The health department now urges that in selecting names for public parks one be chosen for Dr John H Rauch, the father of the park system of Chicago

A Healthful Summer—No such healthful summer appears of record in the history of the city as this of 1904 says the Health Department Bulletin The average August death rate of the last decade was 18 4 per 1,000 of population and the lowest during that period was 14 53 in 1901 For the first twenty days of August the rate was 12 67 and for the week ended August 20 the 437 deaths reported represent an annual rate of only 11 62 These figures show a reduction of 20 per cent from the previous lowest, and of 31 per cent from the previous August average The deaths numbered 437 of which 108 were from intestinal diseases, 59 from consumption 34 from violence, 29 from Bright's disease 26 from cancer and 25 from pneumonia

KENTUCKY

Hospital Opened.—The new Deaconess Hospital, Louisville, was formally dedicated August 4 The building contains 26 rooms, with accommodation for 30 patients

Oil the Mosquitoes.—Dr Fred D Cartwright and the health authorities of Bowling Green have put oil on the various ponds and marshy spots about the city in an endeavor to do away with the mosquito evil

Personal.—Dr W E Gardner Glendale has been appointed second assistant physician at the Central Kentucky Asylum for the Insane, Lakeland——Dr Robert E Brennan, Louisville, sailed for Naples August 10——Dr Hugh R Manning, chief clerk at the Louisville pension agency, has resigned and has accepted the position of chief of clinic of the Hospital College of Medicine.

LOUISIANA

A Third of Million for Tulane—Under the provisions of the will of the late Alexander Hutchinson (referred to in The Journal of May 14) who died in New Orleans, Dec 7, 1902, Tulane University will receive $333,475, to be employed in the upbuilding of its medical department

Personal.—Dr Felix A. Larue, New Orleans, has been reappointed a member of the State Board of Medical Examiners——Dr Louis A Mereaux, New Orleans, has gone to Europe——Dr John N Thomas has been reappointed resident physician of the Mississippi River Quarantine Station

Majority Vote Necessary for Quarantine—At the quarterly meeting of the State Board of Health it was announced that there was no cause for alarm concerning yellow fever in Mexico, and that there was a full understanding with the health officer of Texas A resolution was adopted providing that no quarantine be imposed by the Louisiana State Board of Health unless by a majority vote of its members present at that meeting

Object to Publication of Names and Deeds—The Orleans Parish Medical Society has adopted the following resolutions

Resolved That it is the sense of the Orleans Parish Medical Society that it is inconsistent with the highest ideals of the medical profession for members to permit the appearance in the daily press of articles bearing on their personal attainments or achievements.

Whereas The frequent appearance in the daily press of articles dealing with the professional attainments of members of this society would seem to indicate a growing disregard for medical ethics

Resolved That copies of all articles appearing in the daily press of this city relating to members of this society shall be placed by the secretary in a scrapbook which shall be kept on the president's desk for the inspection of members The book shall be indexed. and any member whose name shall appear therein will have the privilege of attaching thereto a written explanation

MARYLAND

Personal—Dr B Curtis Miller, resident physician of the Western Maryland Hospital, Cumberland, for eight years, has resigned

Typhoid Fever—The last report of the typhoid epidemic at Mt Savage, Allegany County, is 135 cases Physicians say the epidemic is under control At New Creek, near Keyser, there are 32 cases Two deaths have occurred

Baltimore

Suit for Long Service—Dr Adolph G Freedom has brought suit against the estate of John Moan for $7,000 for professional services He alleges attendance from Nov 24, 1900, until death, March 14, 1904, in all not less than 1,700 visits, including 400 dressings of a cancerous foot, and frequent night work

Personal—Dr Page Edmunds has returned from Europe——Dr R. A. Ravenscroft, surveyor of the port of Baltimore, who has been ill with typhoid fever for some weeks at the Maryland General Hospital here, has recovered and returned to his home at Accident——Dr Alexander D Maconachie left, August 25, for a trip to California and Yellowstone Park, stopping at the principal cities of the West

MISSISSIPPI

Infirmary Burned.—The South Mississippi Infirmary at Hattiesburg was destroyed by fire, recently All the patients were removed without casualty The loss was $10,000, with an insurance of $5,250

Must Not Spit in Public Places.—Secretary John F Hunter of the State Board of Health has promulgated an order of the board forbidding expectoration in any public place or building or in any public conveyance

State Association Election—The Mississippi Medical Association has elected the following officers Dr Thomas J Mitchell, Jackson, president, Drs W C Spencer, Verona, Henry Christmas, Tchula, and Charles M Murry, Ripley, vice presidents, Dr J J Haralson, Forest, secretary, and Dr John F Hunter, Jackson, treasurer

NEW JERSEY

Vital Statistics of 1903—The yearly report of the State Board of Health records 31,319 deaths and 37,639 births during the year Consumption is accredited with 3,019 deaths, and pneumonia with 2,421

Gloucester Health Board Legal.—The city solicitor of Gloucester has declared that the present board of health is legally constituted The right of certain members to serve who were not members of the city council was questioned, as this was a requirement of an ancient ordinance An act was provided in 1896 whereby any citizen appointed by the council could serve as a health officer

NEW YORK

Memorial Hospital Open—The Memorial Hospital, Canandaigua, was opened for public inspection August 18 It will soon be ready to receive patients

Sixty Years a Practitioner—Dr William R Wells, Mount Morris, who was graduated from Castleton (Vt) Medical College in 1844, celebrated his 85th birthday August 16

Typhoid in Port Chester—A large number of cases of typhoid fever have developed in this town and its vicinity The state and local health boards believe the epidemic to be due to either impure milk, ice from ponds containing impurities or the contamination of the water supply by Italians living on the outskirts of the town The health officer of the town has ordered the discontinuance of natural ice There have been about fifteen cases so far this month, twice as many as developed last month

New York City

Contagious Diseases.—For the week ending August 13, 1904, there have been reported to the sanitary bureau 328 cases of tuberculosis, with 153 deaths 211 cases of diphtheria and croup, with 23 deaths, 95 cases of measles, with 8 deaths, 86 cases of typhoid fever, with 18 deaths, 50 cases of scarlet fever with 2 deaths 9 cases of varicella 1 death from smallpox, and 24 deaths from cerebrospinal meningitis

Personal.—Dr John Van der Poel sailed on the *Campania* for Queenstown August 20——Dr Menas S Gregory has been appointed acting superintendent of Bellevue and Allied Hos pitals during the vacation of the superintendent, Michael J Rickard——Dr William R Pryor is at St Vincent's Hospital in a precarious condition——Dr Russell Bellamy was seriously injured by being thrown from his pony during a game of polo at Van Cortlandt Park

High Death Rate Among Infants.—Because of the unusual high mortality among babies the health department is taking active measures to lower it by sending circulars of instruction on the proper care and feeding of babies, when asked for physicians and nurses are sent to further instruct and aid the mothers in caring for their children Where there exists several cases of diarrhea in the same family the board of health requests that it be notified in order that they may determine the cause and act accordingly

Device for Street-Car Ventilation—Dr Walker, of the health department of Brooklyn, has devised a simple method for ventilating street cars without causing a draft He had two openings made in the deck sash of a car about ten inches apart, into which were fitted slats to deflect the intake of air to the roof of the car Between these openings a shingle was extended from the side of the car so the wind would strike against it when the car was in motion The principle on which he proceeded was that air would strike the front of the shingle and be deflected into the car, while dust, cinders, etc, would fall to the ground Simultaneously the forward motion would create a vacuum in the rear, which would suck out the vitiated air of the car through the rear slats The cold, fresh air introduced would sink toward the floor and the heated the vitiated air would rise and pass out He had rags and refuse burned in the car until the atmosphere was rendered absolutely unbearable The car was then set in motion at a speed of fifteen to eighteen miles an hour, and within two minutes and a half the air within was fresh and pure

PENNSYLVANIA

Typhoid at West Chester—Several cases of typhoid have appeared in West Chester Dr James C Mewhinney, Spring City, county medical inspector, concludes that the outbreak was sporadic

New Bill to Protect Health—The State Board of Medical Examiners will secure the introduction into the next legislature of a bill giving the board power to recall and cancel any license issued by it whenever it appears that the holder is not a fit individual by lack of proper education moral character, or for the practice of illegal work

Smallpox Throughout the State—Statistics of the State Board of Health show that the total number of cases in the state during July was 94, with 2 deaths Up to August 13 19 cases and one death had been reported In June there were 60 cases and 9 deaths, and in the previous month 274 cases and 21 deaths There were 550 cases and 33 deaths from the disease in May of last year, 506 cases and 33 deaths in June, 359 cases and 63 deaths in July, and 448 cases and 62 deaths in August——Four cases of smallpox, all in one family, were reported in Pottstown August 16 The board of health immediately quarantined the home

Still Fighting Smallpox—Dr Benjamin Lee, secretary of the State Board of Health, in view of the sporadic cases of smallpox throughout the state and to prevent the outbreak of another epidemic with the advent of cold weather has distributed the following circular notice to every school board throughout the state

> You are authorized to address a communication to the parent or guardian of every child of school age in your district to the effect that no child will be permitted to enter school who can not present a certificate of successful vaccination signed by a reputable physician The penalty for failure neglect or refusal to comply with the law is a fine of not less than $5 or more than $100, or imprisonment for a period not exceeding 60 days

Dr Lee asserts that had the law in respect to vaccination been obeyed five years ago, the record of 20,286 cases and 1,585 deaths from the disease since that time would have been almost entirely prevented

Philadelphia

Talks on Consumption—Dr Augustus A Eshner delivered the tenth of a series of plain talks on health arranged by the director of public health, Dr Martin, August 18 The final lecture of the series will be delivered by Dr Edith W Cadwallader, August 25, on the "Connection Between Dirt and Disease"

Pure Food Crusade and Soda Fountains—The pure food commissioners have directed their attention to the dispensers of impure fruit syrups in soda water The so called fruit syrups were analyzed and found to be substitutes Many of them, Chemist Lowall stated, contained materials injurious to health Twenty dealers who conduct these fountains in the southern section of the city, were arrested and held in $500 bail for court

Health Report—The general health of the city continues good and the mortality is below the seasonable average Typhoid fever, however, continues its high standard, 109 cases, with 11 deaths being recorded for the week, as compared with 100 cases and 11 deaths for the previous week The deaths from all causes reached a total of 420, a decrease of 21 over last week and a decrease of 2 over the corresponding period of last year The total number of cases of contagious diseases reported was 181, with 21 deaths, as compared with 194 cases and 16 deaths for the preceding week

SOUTH CAROLINA

Medical Scholarships—The governor has appointed seven young men to scholarships in the Medical College of the State of South Carolina, one from each congressional district

UTAH

Has Appendicitis—Dr Arthur J Holmquist, resident physician at Helper, has been taken to St Mark's Hospital, Salt Lake, suffering from appendicitis

State Society—At the annual meeting of the Utah State Medical Society, the following officers were elected Dr Philo E Jones, Salt Lake, president, Drs Robert S Joyce, Ogden, and John F Critchlow, Salt Lake vice presidents, Dr Walter S Ellerbeck, Salt Lake, secretary, and Dr James N Harrison, Salt Lake, treasurer

Communicable Diseases—The State Board of Health, in its monthly report for May, records 49 cases of scarlet fever in 11 localities, with 3 deaths, 105 cases of smallpox in 13 localities, with no deaths, 24 cases of diphtheria in 8 localities, with 5 deaths, 215 cases of whooping cough in 27 localities, with 21 deaths, 26 cases of measles in 8 localities, with no deaths, 345 cases of pneumonia in 17 localities, with 23 deaths 17 cases of tuberculosis in 6 localities, and 16 deaths and 4 cases of chicken pox in 2 localities, with no deaths

WEST VIRGINIA

Hospital Opens—The Grafton City Hospital, founded by Dr Rawley H Powell, was formally opened August 7

Smallpox—Amos has had 25 cases, with no deaths——One case is reported at Pasco, and precautions have been taken to prevent the spread of the disease

Personal—Dr Samuel L Jepson, Wheeling, has been elected a trustee of Washington and Jefferson College——Dr Edward F Wehner has resigned as superintendent of the Harrison County Hospital, Clarksburg, and has been succeeded by Dr J Wilson of Baltimore

Buys Historic Homestead—Dr M H Crawford, ex surgeon U S Navy, lately resigned, has purchased the famous Falling Spring Farm near Shepherdstown, the old Morgan homestead, where Gen Daniel Morgan encamped before marching his company to the relief of Boston It has been in the Morgan family over 100 years

GENERAL

The American Confederation of Reciprocating Examining and Licensing Medical Boards will meet at the Hamilton Hotel, St Louis, October 25

The American Association of Life Insurance Examining Surgeons will hold its next annual meeting at Portland, Ore July 10, 1905 The membership is now said to number 1,000

Meetings at St Louis—The American Electrotherapeutic Association will be in annual session at the Inside Inn, World's Fair St Louis, September 13 16, and the International Electrical Congress will convene at the Coliseum, September 12 17 The American Obstetrical and Gynecological Association will meet at the Monticello Hotel, September 12 15, and the fifth annual meeting of the American Roentgen Ray Society at the Louisiana Building, 911 North Vendeventer Avenue, September 9 13

Marine-Hospital Service Examination—The next examination of candidates for assistant surgeonships in this service will be held at the Bureau, 3 B Street, S E, Washington, D C Oct 3, 1904, at 10 a m Candidates must be between 22 and

30 years of age, graduates of reputable medical colleges, and must furnish testimonials from responsible persons as to their professional and moral character The examinations are 1, physical, 2, oral, 3, written, 4 clinical On appointment the young officers are, as a rule, first assigned to duty at one of the large hospitals as at Boston, New York, New Orleans, Chicago, or San Francisco Assistant surgeons receive $1,600 The tenure of office is permanent Other particulars have been given in The Journal previously For further information, or for invitation to appear before the board of examiners, address the Surgeon General at the above address

CANADA

Infant Mortality in Ontario—Last year the deaths from infantile diarrhea and cholera infantum in the province of Ontario numbered 790 in all, a little over 2 per cent of the total mortality of the province From all causes there are about 6,000 infants who die in Ontario each year Dr Hodgetts, the provincial health officer, has prepared a set of rules to govern mothers in taking care of their offspring during the summer months

New Brunswick Medical Society—The twenty fourth annual meeting of this society was held at St John, July 19 and 20, Dr J Douglas Lawson presiding Drs G M Woodcock and Daniel McCann Bangor, and Augustin S Thayer, Portland attended as official representatives of the Maine Medical Association The following were the officers elected President Dr A R Myers, Moncton, vice presidents Dr I T Gaudet St Joseph and Dr G N Pearson Sussex secretary Dr I R Murray, Sussex treasurer Dr G C Melvin, St John The next annual meeting will be held in St John

FOREIGN

Cleansing of Cups and Glasses in Restaurants—The medical chamber of the Breslau district recommends that all the dishes be numbered, and be sterilized by heating for one minute to 50 C (122 F) in a 2 per cent soda solution

Tribute to Huchard.—The fourth and last volume of Huchard's great work on "Heart Disease," has just been published, and he has recently been made an officer in the French Legion of Honor His friends seized the occasion to present him with a portrait medal, it bears the device he long ago adopted, "In corde spes vis et vita" After publishing a number of works on neuropathology, his attention has been directed principally to cardiac affections, on which subject he has published many monographs He is now 60 years old and founded both the *Revue clinique et thérapeutique* and the *Journal des Praticiens* He has long been connected with the Necker Hospital

The International Congress of Dermatology in September—A scientific exhibit and also an exhibition of drugs and instruments, is being arranged for this congress which, as already announced, meets at Berlin September 12 to 17 Communications have been promised on "Syphilitic Affections of the Circulatory Apparatus" by von Düring, von Hansemann, Jullien, Lang, Renvers and Thomson Walker, on "Cutaneous Affections in Case of Anomalies in the Metabolism," by L. Duncan Bulkley, Radcliffe Crocker, Jadassohn, von Noorden and Pick, on "Epitheliomata," by Darier, Fordyce, Landgrer, Mibelli, Riehl, Rona and Unna The general review of leprosy will be presented by Neisser Special pains are being devoted to assembling a large number of interesting cases for inspection before the sessions Dr O Rosenthal of Berlin is the secretary general

Seventy-fifth Anniversary of the Brazilian Academy of Medicine—The Academia Nacional de Medicine enters on the seventy sixth year of its existence in a new and commodious building erected by the government at Rio for the meetings of scientific societies and preservation of their collections and archives Its diamond jubilee was celebrated June 30, with much ceremony, and a number of invited guests, including the minister of the interior and other representatives of the government, with ladies, added to the brilliancy of the festival The themes for the prize competitions for 1905 were announced They include fevers endemic in Rio, malaria, surgical treatment of aneurisms, of appendicitis, etiologic rôle of alimentation in Rio, organization of hospital services, indications and contraindications for surgical intervention in obstetrics, parallel study of abdominal and vaginal routes for gynecologic operations, etc The prizes are a gold medal or diploma. Besides these the Alvarenga money prize was declared open to competition by any unpublished work on any subject connected with some branch of medical science Before the festival meeting adjourned a portrait bust of a former president, the late Dr Silva Araujo, was unveiled

Radium and Longevity—We have read with interest the experiments which demonstrated that the larvæ of the meal worm, etc., exposed to the action of the radium rays, were stunted in their growth and remained undeveloped This fact is interesting from another point of view, as Curie has recently pointed out Danysz exposed a number of the larvæ of meal worms to the action of radium last year At the end of a few weeks most of the larvæ had been killed by the rays, but a few had escaped by retreating to the farther end of the vessel, and they are still alive but they are still larvæ The control larvæ passed through their various phases of larval and winged growth, and died of old age, and generations of their descendants have been born and died, but the radium larvæ still persist in their larval stage Only one of the radium larvæ is alive at date of writing, a venerable patriarch, who has survived three times the normal span of the existence of his kind Curie remarks "Imagine a young man of 21 living to be three times the normal period of human existence, retaining at the age of 210 years his youthful appearance at 21! Yet this is what has been observed in the Methuselah meal worm in Danysz' experiment under the influence of the radium rays"

Treatment of Yellow Fever with Antivenin—Bettencourt Rodrigues of S Paulo, Brazil, has been treating a number of cases of yellow fever with polyvalent anti ophidic serum (anti bothropic and anti crotalic serums), and believes that they displayed marked therapeutic value His communication was received with consternation and incredulity in the local medical association, the physicians there generally denying the truth of his three premises, namely, that there is a close relationship between the venoms and microbian toxins, 2, that there is a close analogy between the symptoms of snake bite and those of yellow fever, and, finally, the resemblance and almost absolute identity of the pathologic anatomic findings in the intoxication of yellow fever and in snake bite poisoning The *Revista Medica de S Paulo* of July 15 contains his long array of well sustained arguments to support these premises, and also the counter arguments of his opponents The latter insist that the recovery of all of the 24 patients treated was due to the exceptional mildness of the epidemic in question, as shown by the recovery of large numbers without any treatment also by the fact that the anti ophidic serum in other epidemics in other hands did not give such good results The discussion is an interesting contribution to the literature of the new science, "serology"

LONDON LETTER

New Buildings of St Bartholomew's Hospital.

The foundation stone of the new building of St Bartholomew's Hospital has been laid by the king The hospital now contains 740 beds During the last fifty years more than 7,000,000 persons have been treated About 500 students work within its walls The rapid advance of medical science in recent years has compelled the governors to contemplate the entire rebuilding of the hospital as funds become available So valuable have been the endowments of the hospital that the governors have not found it necessary for 150 years to appeal to the public for funds The most pressing necessity is the construction of a new out patient department at a cost of $500,000

The Profession Asks the Teaching of Hygiene

A large and influential deputation, composed mainly of physicians, waited on Lord Londonderry, president of the Board of Education, to urge the importance of teaching hygiene in elementary schools The deputation was organized in support of a petition prepared by a committee of physicians and signed by 14,718 of them It urged the government to include in the curricula of the public elementary schools and to encourage in the secondary schools such teaching as may lead children to appreciate healthful bodily conditions as regards cleanliness, pure air, food and drink At present such teaching is only optional. Among the deputation were Sir W Broadbent, Sir T Barlow, Sir V Horsley, Sir M Foster, Prof Sims Woodhead, and Dr D Griffiths, president of the British Medical Association Lord Londonderry made a sympathetic reply, but pointed out that there were great difficulties in the way of carrying out the proposals, the principal being the fact that a body of teachers capable of giving the needed instruction does not exist

Fried Fish as a Cause of Typhoid Fever

In a report to the London County Council Mr S F Murphy, the health officer, describes an outbreak of typhoid fever due to fish Since 1899 at least four outbreaks in London have been attributed with much probability to the eating of fried fish In the provinces two outbreaks have been ascribed to this cause Two special features were found in the London outbreaks—multiple attacks in particular houses and an exceptional age incidence, persons between 3 and 25 being attacked in unusual proportion These features occurred in association with two facts—poverty and the eating of fried fish In December, 1903, a group of attacks occurred in the borough of Holborn, which were believed to be due to the eating of fried fish obtained in two particular shops Every other source of infection was excluded In several instances the subjects stated that the fish had a disagreeable odor, and even that it made them sick The cause of contamination of the fish appears to have been imperfect removal of the entrails, which is liable to occur in cheap fish

Opticians and Spectacle Prescribing

A burning question in medical politics just now is the proposal of the 'Company of Spectacle Makers," one of the ancient guilds of the City of London, to grant diplomas in sight testing to opticians This proposal was severely condemned at the recent meeting of the British Medical Association, and the Ophthalmological Society of the United Kingdom has now done likewise, and passed a resolution that "While approving of any measures which tend to increase the efficiency of opticians in their technical work it considers that it would be misleading and dangerous to the public to countenance any proposal to certify as competent to advise and prescribe for defects of vision anyone who has not had an efficient medical and surgical training A diploma such as the Company of Spectacle Makers proposes to grant may lead the public to believe that its possessor is competent to diagnose and treat diseases of the eye Errors of refraction often occur in association with diseases of the eye The mere correction of the former by means of spectacles would ignore a condition which might destroy sight or endanger life Moreover, many errors of refraction can be accurately measured only after the use of a drug which should be used only by a medical man, since its indiscriminate use is calculated to excite one of the gravest diseases to which the eye is liable Finally on general grounds, it is dangerous to encourage the public in the belief that affections of any organ can be safely treated by any one unacquainted with its anatomy and physiology and with the various morbid conditions to which it is liable"

Correspondence.

Club Practice in New Zealand

WHANGARIE, NEW ZEALAND, July 7, 1904

To the Editor —In a recent issue of THE JOURNAL I noticed remarks on club practice Permit me, as one who has passed through the experience, to express myself I am now in a country in which there are many of these friendly societies They are in some respects a very good thing for the working man, and can even provide for an old age pension

In Auckland there are about 3,000 lodge members, many of these are married and have children, every child under the age of 18 comes on the physician's list Take, for example a man 31 years of age who joins the Manchester Unity of Odd Fellows, he pays £3 10s ($17 50) per year, this covers all fees, 6 shillings ($1 50) goes to the chemist 14 shillings ($3 50) goes to the doctor The first fee of £3 10s ($17 50) also acts somewhat as an insurance to the member If he is unable to follow his usual occupation then he receives £1 ($5) per week If it is an accident, then he receives also from the employers' accident insurance, half his usual wages

All the Auckland lodges united, and now have their own dispensary They called for two medical officers, each to receive £500 ($2,500) per year, and to divide the work, confinements, £2 2s ($10 50) and all venereals extra But with the contract I was asked to sign, and the work taking one's time early and late I found a medical man was doing an injustice to himself to his patients and to the medical profession The medical officer had but little time he could spend on each patient Some days my consultations and visits in a radius of 3½ miles would total such a number that they would average each as low as 9 pence (18 cents) I resigned, and the place was filled by a Chicago man

There is another system of club practice which is very commendable In one mining district the miners have a fund formed by deducting a weekly 9 pence (18 cents) from the wage Then, in each case where a medical man is required, he is called and paid from the fund, it is unnecessary for me to say the medico is only called when he is really required—not, as in the other form of club work, called for anything and everything

There has been some effort among the members of the medical profession to combat the growth of lodge work, for example, to limit the membership to those receiving an income less than £200 ($1,000) per year This was unsuccessful I found that I was attending as a lodge member one of the members of the upper house of parliament, and many others with good incomes

The consultation fees in general practice are 5 shillings ($1 25) in the country, 7s 6d ($1 87½) in the city, £1 1s ($5 25) in case of consultants P M KELLER, M D

Perforation in Typhoid

OWATONNA, MINN, Aug 9, 1904

To the Editor —The matter of perforation in typhoid cases has been discussed very extensively of late, both in society meetings, and in the medical journals In your editorial of August 6 you have also referred to the symptoms As the question of operation hinges on the diagnosis, of course for the time being that becomes the most important feature. There is one symptom that I have noticed to be invariably present, both in perforation from typhoid and from gastric ulcer, that I have never heard spoken of During an experience extending over something over 33 years I have seen perhaps some six or eight of these cases, but have never seen a case in which the pulse was not greatly accelerated—running from 160 up to such a rate that it was not susceptible of being counted Another feature is that one may pour all of the stimulants and heart tonics into the patient that one pleases, and they produce no more effect than so much water In most cases that I have seen the respiration has also been accelerated, but not in proportion to the pulse The respiration is also superficial in character I have also noticed quite a sudden drop in temperature THEO L HATCH

Diagnosis of Scarlatina.

PHILADELPHIA, Aug 8, 1904

To the Editor —I was very much interested in your issue of August 6, page 397, *in re* Schamberg's differential diagnosis between scarlet fever and 'scarlatiniform erythema," of which teachers and text books in my student days said nothing Several years ago I was called to see a young lady, about 17 years old, with sore throat, temperature about 100, a somewhat rapid pulse, muscular soreness and a universal red eruption, which I declared to be scarlatinous The mother and daughter both laughed and the former said "Doctor, she has had this several times before, and Dr ——— and Dr ——— have pronounced it each time to be scarlet fever" There was later on some desquamation My patient and I agreed to disagree, though she followed my directions as to treatment, and she recovered, but forgot to pay the bill E W HOLMES

A Request to State Examining Boards—University of Michigan Has Two Departments of Medicine

ANN ARBOR, MICH, Aug 18, 1904

To the Editor —Please permit me through your columns to request the state medical examining boards to distinguish in their reports of examinations between the Department of Medicine and Surgery of the University of Michigan and the Homeopathic Medical College of the University of Michigan These are two distinct schools, with different requirements for admission and with essential differences in the courses offered

ALBUMIN ESTIMATION METHODS AND ERRORS IN PERCENTAGES

Dr I I Schmauss Mankato Minn writes I have frequently been surprised in reading reports of cases of Bright s disease at the amounts of albumin given ranging from a trace to 30 40 50 or even 70 per cent Even a casual glance will show that this is a mistake that there is something radically wrong This becomes more apparent when we consider that the white of egg (almost a semi solid) contains only 22 per cent of solids 95 per cent of which or 20 5 per cent. of the total is albumin Blood and milk comparatively thick fluids contain only from about 25 to 12 per cent of solids respectively Even cream shows only about 34 per cent Again blood with a specific gravity of 1055 to 1060 has less than 25 per cent of solids milk with a specific gravity of about 1030 shows only about 22 per cent and saccharin urine with a specific gravity of 1030 to 1060 generally yields only 3 to 6 per cent practically never over 10 per cent of sugar Now then when we consider these facts can a nephritic urine a thin watery fluid with a specific gravity ranging from 1010 to 1030 (most of this due to the ordinary urinary constituents—urea uric acid etc) show or contain 30 or 40 or 50 or 70 per cent of albumin I can not understand how such result can be reached and be continually reported by many different authors Because of the latter fact it can not be due to a typographic error Dr G M Edebohls in The Cure of Chronic Bright s Disease by Operation *Medical Record* Dec 21 1901 says in one place The amount of albumin in the urine is at present 40 to 50 per cent as against 50 to 70 per cent prior to the operation Dr A H Ferguson page 12 The Jour A M A July 4 1903 says Urine albuminous 30 per cent eighteen days after operation only about 0 5 per cent The same author in an article in The Journal April 16 1904 gives the percentage of albumin present in the urine of two of the cases as 36 and 35 per cent respectively These same proportions are given in a similar article describing the same cases in the *Medical Standard* of August 1904 These are only a few prominent instances of the many which I have observed June 6 1904 I wrote to Dr —— as follows Dear Doctor Having myself operated a case of chronic Bright s disease I always read with interest the reports of such cases In going over your valuable article I noticed the percentage of albumin given as 36 and 35 per cent respectively I have seen such percentages and even up to 50 or 70 per cent (an impossibility of course) given on other occasions Now either these various writers have made a mistake wrote 30 or 50 or 70 per cent instead of 0 30 0 50 or 0 70 per cent or the printers committed such an error or I am in error and so is Simon s Chemistry Von Jaksch Esbach etc. Simon s Chemistry for instance says The average amounts of albumin present in acute cases of albuminuria is 0 1 to 0 5 per cent. rarely over 1 per cent though it may rise to 4 per cent. This corresponds with my findings While interne at Cook County Hospital Chicago I examined many specimens of urine containing albumin In none did I ever find so much present as in the case I have operated on This urine when boiled would become almost solid on addition of nitric acid coagulation would occur to the top of the urine But 1 5 per cent was the highest I obtained—according to Esbach s method the one most commonly employed. As I understand it the figures 1 to 7 on this instrument do not mean 10 to 70 per cent. but 0 1 to 0 7 per cent or from 1 to 7 per 1000 which is the same Now Doctor this is a very important matter from a scientific standpoint and I would be very much obliged to you if you would kindly write me a few lines to help clear this up or stating by what method you estimate the percentage of albumin I regret that I did not receive a reply from Dr —— hence I have to look elsewhere for this information which I am sure will also interest other readers of The Journal

Answer.—Your criticism of the percentages of albumin given by various writers is both just and timely There is no standard in general use and in consequence there is great difficulty in interpreting the statements of medical writers The estimation of dry albumin is not possible for any one except a chemist, and in consequence various means of proximate estimation have been devised. Probably the usual percentage is based on a rough estimate of the amount of precipitate as compared with supernatant liquid in a newly precipitated mixture—say after standing a minute Figures based on this method have the same value as such statements as large amounts considerable etc. In our opinion the next most frequent method of estimation is by the centrifuge The usual reading is given as percentage whereas it should be volume percentage Purdy demonstrated that this is fairly accurate if the machine had arms 6¾ inches long and was swung for three minutes at the rate of 1,500 revolutions per minute Furthermore if the volume percentage be divided by 10 it would give the grains of dry albumin per fluid ounce For example 10 per cent volume percentage equals 1 grain of dry albumin to each ounce of urine A large number of the percentages published are based on estimation with the Esbach albuminometer Your criticism of a frequent erroneous reading of this instrument is timely The figures 1 to 7 are intended to show grams per liter A urine which precipitated to 7 should be read as 7 grams to 1000 c c or 0 7 of 1 per cent A much more accurate method and one not much more difficult, is Brandberg s modification of Robert s method The principle of this test is a determination of the weakest dilution of the urine which will give a Heller s reaction in 3 minutes We would suggest to writers that they qualify their statements of percentages by specifying the method used

THE RIGHTFUL PRECEDENCE OF THE FAMILY PHYSICIAN

I of Illinois writes I wish to submit a question in regard to medical ethics A child was bitten by a dog and brought to my office but I was temporarily absent and the child was taken to a drug store and another physician summoned who came and dressed the injuries I have been the family physician since the family came here and that evening the mother saw me related the story of the case and told me of the treatment which I approved and she said she wished I could see the wounds and asked if I would go over to the other physician s office with her the next morning and then as she passed my office. she called and asked me to go with her that I might see the extent of the wound and judge of its appearance and danger Now it was not a question of treatment or anything except that I might see the wound. Was there anything unethical in my going over with her? The attending physician took it as a serious offense refused to further touch the case and acted terribly insulted His conduct was not to be excused even if I were in the wrong but I want your opinion as to the ethical right or wrong of my going to his office under the circumstances.

Answer.—As before noted in this column we can not undertake to act as arbiter of the disputes of physicians In order to render judgment in an individual case both sides must be heard—circumstances often change shape when viewed from another point or through other eyes Assuming then that our correspondent states a somewhat hypothetical case there is but one answer as to the proper course to be pursued Our correspondent had a perfect right to see the case and the other physician had no justification in professional custom to become offended at the presence of the family physician In fact, among medical men who find pleasure in the niceties of conduct one who in an emergency is called to a case in the absence of the family physician always retires from attendance on the case when the family physician returns Judged by such a standard the physician of whom our correspondent complains erred twice First in keeping the case after the family physician was at hand and second in finding any fault with the mother s request that the family physician be present at the dressing of the wound

USE OF THE HOLLOW RING PESSARY

W asks for a few pointers on the use of the hollow ring pessary He says it is a pessary filled with air looking for all the world like an old fashioned doughnut and wishes to know its name mode of application how long can it be left in etc

Answer —There is a hollow rubber ring pessary already inflated with air (Meyers) a hollow rubber ring pessary to be inflated by means of a tube (no name) and a solid soft rubber ring pessary (Meyers) They are sometimes useful in a prolapse of the uterus that is not held in position by a hard rubber pessary although the latter is to be preferred when servicable on account of greater cleanliness The soft rubber pessary is put in place by first narrowing it by pressure between the thumb and forefinger carrying it into the vagina and up to the vault, then by bimanual manipulation seeing that the uterus is in place and the rubber ring encircling the cervix. Daily douches should be recommended while the pessary is worn, and it should be removed and cleansed at least once a week as it has a great tendency to become foul

MEMBRANOUS DYSMENORRHEA.

D B C of California writes I have a case of membranous dysmenorrhea in a young married woman, aged 22 She has suffered from this since she first menstruated at 14 or 15 years of age. At times the membrane is complete, while at other times it comes away in strips Her suffering at these times is very severe Her health between her menstrual periods seems normal On examination the pelvic organs appear normal in size and position and as far as I am able to ascertain free from inflammation She is however of a nervous temperament Will you kindly give me in The Journal the cause prognosis and treatment of this disease? I have used acetanilid, gelsemium morphin etc. but with only partial relief Would pregnancy be likely to relieve this most painful condition?

Answer —Membranous dysmenorrhea is thought by some to be a result of endometritis, by some, a monthly abortion, and by some, a monthly casting off of membrane is thought to be normal and an event which gives trouble only when inflammation is present or when an abnormally large piece is passed It should be mentioned that some think that neither of these conditions account for all the cases The prognosis is not good as to a ready cure Pregnancy might help the case but these cases have little tendency to become pregnant and if they do become pregnant, abortion is apt to follow Probably the most reliable treatment would consist of curettage and correction of anteflexion, if present In some cases a second curettage has had to be done a few months later The beneficial effect of diet out of door life, baths, douches, etc should not be overlooked

A GENERAL UTILITY DOCTOR

'Speaking of letter heads, writes a correspondent, I send you one to publish in your Queries and Minor Notes columns that shows that we have one physician here who covers the whole field The letter head has in the left upper corner

Local Surgeon ——— ——— R R Co
Local Adjuster ——— ——— Accl Insurance Co
Medical Examiner —— — ——— Insurance Co
Medical Examiner ——— ——— Insurance Co'

On the right upper corner

President ——— Telephone Co
Cap Stock $10 000 ———, Ill
President ——— Irrigation Co
Cap Stock $200 000 ——— Texas
President ——— Chemical Co
Capital Stock $25 000 ——— Ill
Director ——— Crude Oil and Gas Co
Capital Stock $1,000 000 ——— Ariz

A page advertisement in a local literary magazine informs us that the same physician is Oculist Physician and Surgeon" That 'All Diseases of the Eye Treated and glasses fitted by the most approved method that he gives Special attention to all static electrical and x ray work The doctor is said to be a member of his county state and national societies

ADRENALIN IN HYDROCELE

Dr B F Bennett Trenton Tenn writes I noticed in The Journal June 4, 1904 page 1496 an editorial on injections of adrenalin in serous cavities I have a case of hydrocele I want to try it on if you will kindly tell me if I should use the 1 1000 without dilution and the amount to use

Answer —We hesitate to advise the use of this powerful drug in the case mentioned Several cases of anemic necrosis have occurred in its use elsewhere, but no data are to be had as to its employment in hydrocele If every other surrounding circumstance is favorable, and if our correspondent is still of a mind to try the measure 10 to 20 minims of a 1 to 5000 solution may be cautiously injected and the results noted before any repetition The preliminary withdrawal of the fluid in the hydrocele should not be complete, a small portion being left to mingle with the injection

GO TO THE WORLD'S FAIR

Dr W W Keen, Philadelphia, writes from Colorado Springs concerning the educational exhibit at St Louis as follows No such exhibit of educational methods and means of instruction in medicine (especially by Germany) has ever been made It impressed me greatly and especially should stimulate all our medical schools and teachers to imitation and to surpass what they have done if possible If you have not already done it I hope you will urge your readers and especially all teachers of medicine to visit the Fair, especially the education building and particularly the German and the Japanese exhibits Next to Germany Japan has done the most What she is doing in war she is doing in medicine.

Answer —A continued article on the Fair appeared in The Journal July 16 and 23

STATE BOARDS THAT RECIPROCATE

Several Correspondents The following states provide for reciprocity in their laws or else have authority to so provide vested in their state examining boards Wisconsin Indiana, Michigan, Ohio Iowa Kansas Illinois Nebraska, Kentucky Pennsylvania (eclectic) Maryland Georgia Oklahoma New Jersey and Maine The method of reciprocity is not the same in all Some of these reciprocate on the basis of Qualification 1, some on the basis of Qualification 2 and some on both These qualifications appeared in The Journal, August 13, page 481

DEALER IN MEDICINE AND SURGERY

An Indiana physician has the following corner grocery store announcement on his letter heads Dealer in Medicine and Surgery Specialties Diseases of Women and Childbirth"

Willis Le Baron Hale, M D, North Attleboro, Mass, to Mrs Georgie Powell Hopkins, at Onancock, Va, August 9

Deaths.

Ralph Chandler, M D Rush Medical College, Chicago, 1886, a member of the American Medical Association, Wisconsin State Medical Society, Milwaukee County Medical Society, and Association of Military Surgeons of the United States, captain and assistant surgeon in the Wisconsin National Guard for eighteen years, and surgeon of the First Light Battery, one of the most brilliant young surgeons of Milwaukee, for several years a member of the staff of the Johnson Memorial Hospital, died at Knowlton Hospital, Milwaukee, August 12, two days after an operation for intestinal obstruction, aged 41 At the funeral the honorary pallbearers were representatives of the medical fraternity, the Loyal Legion and the Wisconsin National Guard, while the active pallbearers were non commissioned officers of the First Light Battery, in which he had been an officer for eighteen years

John Womack Hayes, M D Washington University School of Medicine, Baltimore, 1870, a member of the American Medical Association, president of the Tri State Medical Association of Mississippi, Arkansas and Tennessee, past president of the Arkansas State Medical Society, Carroll County Medical Society, and Lee County Medical Society, member of the Tri County Medical Society, who, on account of persistent overwork, had broken down so that an operation was necessitated in February, died by taking sixty grains of morphin, at his home in Eureka Springs, Ark, August 8, aged 56

Henry C Coty, M D University of Louisville, Ky, 1880, of Shreveport, La., a member of the Louisiana State Medical Society and Shreveport Medical Society, coroner of the parish of Caddo, and local physician for the Texas and Pacific, and Houston East and West Texas Railroad, died in New York City, August 10, from uremia, aged 45 The Shreveport Medical Society, at a special meeting, August 13, adopted resolutions of respect and sympathy

Albert W Warden, M D New York University, New York City, 1880, of Union Hill, Weehawken, N J, a member of the American Medical Association, died from septicemia, due to an operation wound, August 9, at the Presbyterian Hospital, New York City, after an illness of three weeks, aged 47 He was at one time assistant surgeon in the National Guard of New Jersey and assigned to the Ninth Infantry

Frank Howard Payne, M D Rush Medical College, Chicago, 1874, a member of the American Medical Association, Medical Society of the State of California, and Alameda County Medical Society, a member of the faculty of the College of Physicians and Surgeons, San Francisco, died from erysipelas, August 8, after an illness of one week, at his home in Berkeley, Cal, aged 53

George T Heston, M D University of Pennsylvania, Philadelphia, 1852, one of the oldest physicians in eastern Pennsylvania, died at his home in Newtown, August 15, from Bright's disease, aged 78

Jonathan S Whitely, M D Ohio, 1878, of Corry, Pa, and secretary of the local board of health, was drowned while fishing on Findlay's Lake, N Y, July 27, aged 48

John J Covert, M D University of Michigan, Ann Arbor, surgeon of volunteers in the Civil War, died at his home in Lawrenceville, Pittsburgh, Pa, July 12, aged 81

Thomas B La Rue, M D University of Nashville Medical Department 1852 who retired from practice in 1902, died at his home in Smith's Grove Ky, July 19, aged 83

George A. Carlin, M D University of Wooster Cleveland, 1872, died at his home in West Salem, Ohio, July 28, from diabetes after an illness of several months, aged 59

Orville Follett, M D Medical School of Maine at Bowdoin College, Brunswick 1841, died at his home in Normal, Ill, August 12 after a protracted illness aged 88

Charles Martin Schafer, M D Western Pennsylvania Medical College, Pittsburg 1900, died at his home in Pittsburg Pa, July 25, after an illness of six weeks, aged 27

Emil H Schellack, M D St Louis College of Physicians and Surgeons, 1886 died at his home near Galena, Kan, August 9, from septicemia, after a long illness, aged 60

George V Wenner, M D Medico Chirurgical College of Philadelphia, 1896, died from the effects of an overdose of cocain, at his home in Milford, N J, July 23, aged 40

Charles E Cockey, M D University of Maryland Baltimore 1866, secretary to the Board of Health of Queen Anne County, died at Queenstown, Md, July 31, aged 62

Arthur Napoleon Herwig Brown, M D Memphis (Tenn) Hospital Medical College, 1893, died at his home in McDonoughville, La, July 30, after a long illness, aged 31

Charles H McCann, M D Cooper Medical College, San Francisco, died at the American Hospital, City of Mexico, July 8 after an illness of five days, aged 40

John H De Puy, M D Willoughby (Ohio) University Medical Department, 1846, died at his home in Wabash, Ind, July 20 after a short illness, aged 83

Peter Sutton, M D, a retired physician of Adrian, Mich, died at his home in that city from senile gangrene, after an illness of six weeks, August 1, aged 78

James H McCullough, M D Trinity Medical College, Toronto, Ont., 1883, formerly of Owen Sound, Ont, died at his home in Battleford, N W T, July 12

Robert L Hadley, M D Medical Department of the University of Tennessee, Nashville, 1878, died at his home in Edgefield, Tenn, July 10, aged 65

George P Johnson, M D Albany (N Y) Medical College, 1867, was found dead in bed at his home in Mexico, N Y July 17, from apoplexy, aged 59

David L Bailey, M D New York University, New York City, 1875, died recently at his home in Carbondale, Pa, from septicemia, due to a pin scratch

Ivo W Buddeke, M D Ohio, 1875, died, July 11, in a congestive chill at his home in Memphis, Tenn, after an illness of only a few hours, aged 52

William Allen Reed, M.D Rush Medical College, Chicago, 1882, died at his home in Necedah, Wis, August 6, from Bright's disease, aged 46

David C Spalding, M D University of Michigan, Department of Medicine and Surgery, 1858, died at his home in Lyons, Mich, July 14, aged 70

William H Renner, M D University of Maryland, Baltimore, 1870, died at his home in Industry, Kan, August 5, from asthma, aged 62

R. Irvin Walton, M D Medical College of Georgia, Augusta, 1877, of Danburg, Ga, was shot and instantly killed near Tignall, Ga, July 6

James S Gayer, M.D College of Physicians and Surgeons, Keokuk, Iowa, 1878, died at his home in Plainville, Ill, February 25, aged 60

Van McHenry, M D Ohio, died at his home in Plainville, Ind., July 11, from kidney and liver disease, after an illness of three weeks, aged 75

Thomas Luther Thomason, M.D Baltimore Medical College, 1896, died at his home in Atlanta, Ga, July 29, after an illness of two weeks

Lyndhurst C Dodge, M D Albany (N Y) Medical College, 1862, died suddenly at his home, Rouse's Point, N Y, August 12, aged 63

Anthony Lechley Pillow, M D Jefferson Medical College, Philadelphia, 1845, died at his home in Columbia, Tenn, July 14, aged 85

Memory Lee Doom, M D Ohio, 1874, died at his home in Tacoma, Wash, June 30, from heart disease, aged 70

W B Dudley Jackson, M D Hospital College of Medicine, Louisville (Ky), 1875, died at his home in Brick Church, Tenn, August 7

Eli J Zook, M D Jefferson Medical College, Philadelphia, 1878, died suddenly at his home in Newville, Pa, July 10, aged 60

Henry A Jendrault, M D Albany (N Y) Medical College, 1882, died suddenly at his home in Dover, N H, July 11, aged 58

Alonzo D Kingsley, M D Massachusetts, 1847, died at his home in Muskegon, Mich, July 18, after an illness of one week, aged 82

John C Campbell, M D Ohio, 1874, died suddenly from hemorrhage of the stomach, at his home in Kenton, Ohio, July 22, aged 60

Jacob Graul, M D Germany, 1860, died at his home in St Louis, July 25, from dropsy, after an illness of several months, aged 70

John McSimpson, M D Indiana, 1888, of Chicago, was struck by a train at Pullman, Ill, and instantly killed, July 30, aged 58

George I Rice, M D Pennsylvania Medical College, Philadelphia, 1858, died at his home in Princeton, Ill, February 22, aged 72

W L Burns, M D, an aged physician of Maxton, N C, was found dead from exposure on the outskirts of the village, July 23

Osmer W Lounsberry, M D Ohio, 1874, died suddenly at his home in Wyoming, Ohio, August 5, from gastroenteritis, aged 68

Garrett Anderson, M D New York University, New York City, 1860, died at his home in Shacklefords, Va, August 4, aged 65

Samuel F Williams, M.D Medical College of Indiana, Indianapolis, 1883, died at his home in Casey, Ill, March 16, aged 50

Macon M Kilpatrick, M D Baltimore Medical College, 1892, died at his home in White Plains, Ga, July 18, after a long illness

Joseph L Wistein, M D Rush Medical College, Chicago, 1890, died at his home in Chicago, in April, 1903, aged 43

Nicholas Harrington, M D Starling Medical College, Columbus, Ohio, died, June 27, in Palermo, Kan, aged 79

Margaret Grey, M D Illinois, 1897, died in Chicago, August 11, from injuries sustained in a fall last February

W H Lippett, M D, of Roanoke, Va., died at the Roanoke Hospital, July 28, from typhoid fever, aged 28

Alexander S Campbell, M D Indiana, 1897, of North Liberty, Ind, died in Seattle, Wash, August 5, aged 87

A. J Atkinson, M.D, surgeon during the Civil War, died at his home in Lewistown, Pa., July 12, aged 83

L W Ellsworth, M D, formerly state senator, died at his home in Rappsburg, Ohio, July 25, aged 81

William B Kenyon, M D Pennsylvania, of Buffalo, N Y, died recently at Dansville, N Y, aged 57

John Needham, M D Ohio, 1864, died at his home in Glendora, Cal, July 8, from cancer of the liver

William J Patterson, M D, 1894, died at his home in Slippery Rock, Pa, from cancer, July 16, aged 37

Mary E Patridge, M.D New York, 1884, of Burlington, Vt, was drowned recently at Red Rocks, Vt

A. C Herman Schneider, M D Pennsylvania, 1900, died at his home in Moores, Pa, August 5, aged 25

Jacob Mellinger, M.D, a prominent chemist of Baltimore, died at his home in that city July 26

Charles S Rush, M D Pennsylvania, 1867, died at his home in Metropolis, Ill, July 28, aged 75

James Hayton, M D Illinois, 1877, died at his home near Carbondale, Ill, August 7, aged 88

Guy T Adams, M D Illinois, 1897, died at his home in Mendota Ill, May 31 aged 37

D W Strader, M.D, died at his home in Hiseville, Ky, July 18, after a long illness, aged 80

Rudolph D Baird, M D Colorado, 1898, died at Denver, Colo, August 5, from consumption

Harlan Harrison, M D Ohio, 1852, died at his home in Union City, Ind July 19 aged 79

Isaac C Detwiler, M D, Philadelphia, 1861, died at his home in Manheim, Pa, August 14

Milton R Maxson, M D Illinois, 1900, died at his home in Chicago, July 26, aged 60

H H Fledder-Johann, M D, died recently at his home in New Knoxville, Ohio, aged 88

Ralph Lee Cooper, M D, 1861, died at his home in Ogontz, Pa, August 2, aged 77

John Walters, M D Illinois, 1896, died at his home in Joliet, Ill, March 25, aged 52

John E Whitecraft, M D Illinois, died in Pawnee County, Kan, June 21, aged 66

Lewis J Field, M D Illinois died at his home in Dietrich, Ill, March 22, aged 83

Ferdinand Hoffmann, M D Illinois, 1897, died at his home in Chicago, July 10

Emma N Warne, M D Illinois, 1897, died Oct 7, 1902, aged 50

Book Notices.

A SYSTEM OF PRACTICAL SURGERY By E von Bergmann, M D, P von Bruns M D and J von Mikulicz, M D Volume III Translated and Edited by William T Bull M D, Professor of Surgery, College of Physicians and Surgeons, Columbia University New York, and John B Solly, New York Surgery of the Extremities Cloth Pp 918 Price $6 00 New York and Philadelphia Lea Brothers & Co 1904

When this work appeared in the original but a short time ago it was at once recognized as a work of great merit The first edition was soon exhausted and a second revised edition of four volumes at once issued This is an English translation of the second German edition, and the first three volumes are already out Volume 1 takes up surgery of the head There are no opening chapters on general pathology, aseptic methods, etc, as is so common in similar works, but the authors enter at once on their subjects Vol 2 treats of surgery of the neck, thorax and spinal column, and Vol 3 of surgery of the extremities The subjects are covered extensively, yet concisely, and when operative procedures are discussed more attention is given to the careful description of some one standard method than to briefly describe several methods The work is extensively illustrated with numerous cuts and colored plates most of which are new It is without doubt the best modern text book on surgery, and the profession is to be congratulated on having such an excellent English translation

THE DOCTOR'S RECREATION SERIES (In Twelve Volumes) Vol I The Doctor's Leisure Hour Facts and Fancies of Interest to the Doctor and His patient Arranged by Porter Davies M D Cloth Pp 352 Vol II The Doctor's Red Lamp A Book of Short Stories Concerning the Doctor's Daily Life Selected by Charles Wells Moulton, General Editor of the Series Cloth Pp 343 Price $2 50 per volume Chicago, Akron, New York The Saalfield Publishing Co 1904

Here is something new—at least, as far as we are aware The first two volumes of the Doctor's Recreation Series promise that the set will be a very interesting addition to the physician's library Volume 1 contains a wealth of humorous short stories, puns and anecdotes of a medical nature The selections are very well made and many a delightful interval may be passed in their perusal

Volume 2 is a book of several longer stories concerning the physician's daily life The volumes are large and well bound and are illustrated with reproductions of famous paintings of appropriate subjects It will be interesting to watch for subsequent volumes of this series

THE PRACTITIONER'S GUIDE By J Walter Carr M D (London) F R C P Physician Royal Free Hospital T Pickering Pick F R C S Consulting Surgeon St George's Hospital and Victorian Hospital for Children Alban H G Doran F R C S Surgeon to the Samaritan Free Hospital Andrew Duncan M D B D (London) F R C S, M R C P Physician Branch Hospital Seamen's Hospital Society Cloth Pp 11[illegible] Price $8 00 New York London and Bombay Longmans Green & Co 1902

The Practitioner's Guide is a book of reference in the form of a dictionary, in which the busy practitioner may find with little loss of time the salient points regarding the symptoms, differential diagnosis and treatment of diseases The etiology is only briefly referred to for obvious reasons A considerable amount of space is devoted to gynecology Obstetrics is entirely omitted Considerable space is given to tropical diseases which of late years have excited more interest in the medical world In the consideration of surgery only the emergency operations are described in detail

Miscellany.

Case of Genuine Recurrence of Cholelithiasis—Klemperer of Carlsbad reports a case in the *Prager medicinische Wochft* No 28, 1903, in which the patient has voided more than a hundred stones, commencing about three months after cholecystectomy The biliary passages were apparently cleared out during this operation, and even if a few stones had been left behind, they would not explain the large number passed since

Permanently Barred from Pennsylvania—At the meeting of the Medical Examining Board of Pennsylvania, three candidates for license to practice were expelled for cheating The medical council has decided to bar these candidates permanently from future examinations This is in just recognition of the fact that character is equally important as knowledge in the practice of medicine and the decision marks an important step in the general advancement of the profession under the influence of the examining boards—*Penn Med Journal*

Notes on American Hospitals—Campbell Douglas, L R C P Ed, in an article in the *Glasgow Medical Journal*, February 1904, says

> The American medicine man of to-day is a worthy descendant of all the great men of the past young and keeping young even when his years are many restless energetic bold he is ever striving toward an unseen ideal He is like the art he practices in a transition stage sifting the great mass of chaff for the few grains of wheat and with a resolute determination to find them He is jogging along in no rut he is traveling over unbroken ground, with all the magnificent energy of his race The future of our profession seems well assured in the hands of such a man and the day may come I think when the younger members of our calling will go to extend their knowledge and finish their education not in Berlin or Paris or Vienna but in New York and Baltimore and Chicago

Danger of Lumbar Puncture in Case of Brain Tumor—Masing reports in the *St Petersburger med Wochft*, of Jan 16, 1904, from Dehio's clinic, the case of a young woman exhibiting headaches and disturbances in vision—diagnosed as due to a brain tumor in the right frontal lobe Great relief was experienced after withdrawal of 300 c c of blood Four days later 002 gm of pilocarpin were injected Three days after this 30 c c of cerebrospinal fluid were withdrawn by lumbar puncture The pressure was about 10 to 15 c c at first but dropped to zero Nausea followed at once with convulsions and the patient died in fifteen hours The necropsy revealed a recent rupture of an arroded blood vessel in a microscopic sarcomatous focus

Akathisia—The term akathisia has been applied to a syndrome consisting in an inability on the part of the patient, with preservation of consciousness, to remain seated, on the one hand, in consequence of repeated, involuntary, compulsory attempts to jump up, and on the other hand, as a result of an impulse to alternate the sitting with the erect posture The impulse is at times so powerful as to compel the patient to grasp some object firmly to prevent himself from rising Dr Ladislaus Häskovec (Wiener medizinische Wochenschrift March 26, April 2, 1904) has reported two instances of the disorder, and has suggested the name for it One of these occurred in a case of hysteria and the other in a case of neurasthenia Häskovec considers the affection a functional disturbance of a cortical origin, constituting in the first case a form of spasmodic tic or myoclonus, and in the second a transition to an emotional disorder An instance similar, though not identical in character, has been reported by Raymond and Janet (Nouvelle Iconographie de la Sâlpetrière, June, 1903) in a case of occupation neurosis in a goldsmith attended with a phobia

State Boards of Registration.

COMING EXAMINATIONS

New Hampshire State Medical Board September 8 9 State House Concord Regent Channing Folsom Concord,

Massachusetts Board of Registration in Medicine September 13 14 State House Boston Secretary Edwin B Harvey M D Boston

Missouri State Board of Health September 19 21 St Louis Secretary W F Morrow M D Kansas City Mo

Iowa State Board of Medical Examiners September 21 22 Capitol Building Des Moines Secretary J F Kennedy M D Des Moines.

Territorial Medical Examining Board of Oklahoma September 28 Guthrie Secretary F I Cowdrick M D, Enid

Ohio Report —The report of the Ohio State Board of Medical Registration and Examination furnished by the secretary was complete, but, through some oversight when printed in THE JOURNAL, August 6, page 415, the following data were omitted

PASSED

College	Year Grad	Per Cent
Bellevue Hospital Medical College N Y	(1897)	80
Miami Medical College	(1903)	91

(1904) the grade of 82 was reached by three 85 by two 89 by three 91 by four 92 by one and 94 by one

The general average attained by all representatives of Miami was 88 2

South Dakota July Report —Dr H I McNutt secretary of the South Dakota Board of Medical Examiners reports the written examination held at Watertown, July 13 and 14 1904 The number of subjects examined in was 10 total questions asked, 79, percentage required to pass, 75 The total number examined was 27, of whom 19 passed and 6 failed * The following colleges were represented

PASSED

College	Year Grad	Per Cent
Rush Medical College Chicago	(1900) (1903) (1904)	84 3 79 5 87 9 87 7 87 7
Northwestern University Chicago	(1903) (1904)	70 8 75 7
Creighton Medical College Omaha	(1903)	82 9
Bennett Coll of Ecl Med and Surg Chicago	(1904)	90 7 75 3
College of Physicians and Surgeons Chicago	(1904)	79 7 77 9 83 3 81 8 81 3 90 3 84 5
Sioux City College of Medicine	(1902)	83 2
Hamline University Minneapolis	(1903)	76 7†

FAILED

College	Year Grad	Per Cent
Rush Medical College	(1889) (1896)	48 6 64 3
Hamline University	(1903)	69 3
University of Vermont	(1890)	60 7
Memphis Hospital Medical College	(1904)	73 3

* Two who passed the examination were not granted licenses pending further investigations and one who failed did not give satisfactory references

†Second examination

This was the regular semi annual meeting The old officers were re elected. A resolution favoring reciprocity in examination with other state boards was passed, also a resolution defining the minimum qualifications of graduates from medical schools to be considered in good standing by this board

Recent Pennsylvania Report —The report of the Pennsylvania State Board of Medical Examiners, just completed shows that of 379 applicants examined, 73 failed to meet the requirements, or 19 41 per cent of the whole The usual percentage of failures is 13 or 14 Analyzing the records of the 73 applicants who failed, 10 failed in two other examinations, and 5 came up for a second re examination One had failed on 4, another on 5 and another on 7 previous occasions One had failed before and also had been expelled for cheating Dr Henry Beates, president of the board said that the large percentage of failures discloses the fact that some medical colleges still confer the doctorate on illiterate and ignorant individuals

Georgia Will Reciprocate —During the last hours of the session of the Georgia legislature—thus writes Dr I H Goss, president of the Regular Board of Medical Examiners of Georgia—by the kind efforts of one of our representatives, Dr L G Hardman of Commerce, Georgia, we got an amendment to our medical law allowing reciprocity with all states which require the same standard as that of Georgia Our state requires a diploma from a recognized college—one requiring three or more years of study, and one in good standing in the college association—and examination in anatomy physiology, materia medica and therapeutics, chemistry, obstetrics, surgery, gynecology, practice diagnosis and pathology, and the applicant is required to make not less than 75 per cent on a general average, and a fair average on all the branches The next meeting for permanent license will be held in Atlanta at the Capitol, Oct 11 1904

The Public Service

Army Changes

Memorandum of changes of stations and duties of medical officers U S Army week ending Aug 27 1904

Noble R L asst surgeon relieved from U S General Hospital Washington Barracks D C and ordered to U S General Hospital Presidio of San Francisco for duty

Gregory Junius C asst surgeon relieved from duty at U S General Hospital Presidio of San Francisco and assigned to duty as surgeon on the *Sheridan* during voyage to Manila and on arrival to report to commanding general Philippine Division for assignment to duty

Davis Wm R asst surgeon relieved from duty on *Sheridan* and to report to the military secretary for further orders

BRITISH MEDICAL ASSOCIATION

Seventy Second Annual Meeting, held at Oxford, July 26 30, 1904

(Continued from page 562)

Address in Surgery

The address in surgery was delivered by Sir William Macewen, Glasgow He spoke first on the cerebral invasion of pathogenic and pyogenic organisms He referred to the localization of brain abscess, saying that prior to the advent of cerebrospinal surgery abscess of the brain was regarded as of a pyemic nature and occurring by metastasis Where abscess occurred secondary to a primary pyogenic cranial lesion, some were inclined to believe that it was due to a pyemic manifestation and could occur in any part of the brain without relation to the primary lesion Early observation showed that this view was erroneous and that all brain abscesses arising in the cranial cavity, if not in direct contact with such foci of infection, were at least in contact with the infective path which lay between the primary focus and the abscess He said that if the cerebral abscess remains untreated and continues to grow, it may implicate other regions of the brain For example, in an intracranial abscess resulting from ear disease the abscess will form within a limited area of the middle ear, extension being limited by the anatomic condition of the parts and the prior pathologic encroachments If the micro organisms enter the cranium by means of the tegmen, abscess of the cerebellum is frequent, while if they have traveled by way of the internal auditory meatus leptomeningitis is the result, with early involvement of the medulla and respiratory centers Tuberculous meningitis may occur without perforation of the tympanic membrane and without swelling over the mastoid In several cases the internal auditory meatus was the channel by which the tuberculosis spread from the middle ear to the membranes in the cranial cavity

He also said that tuberculosis of the mastoid may become a menace to life by a dissemination through the sigmoid sinus to other parts of the body In a number of cases the lumen of the sinus has been invaded by the tuberculous granulation tissue

THE RECOGNITION OF RESPIRATORY AND CARDIAC REFLEXES

He spoke next on the recognition of respiratory and cardiac reflexes in anesthesia caused by peripheral impressions on the pudic nerve, and referred briefly to a case in which an alarming spasm of the glottis occurred when the sphincter ani was stretched during an operation for hemorrhoids

CHOICE OF SUTURE MATERIAL.

In the choice of suture material he said that, though many surgeons regard asepsis as the sole requirement, it is in fact only one of many requirements He said that the material must be strong enough to keep the tissues in contact long enough for union to take place, as well as being capable of being absorbed He condemned buried non absorbable suture material He spoke at some length on the time required for different tissues to unite and the time required for catgut and other sutures to be absorbed, illustrating his remarks with microscopic sections He also emphasized the fact that, when absorbable sutures are used, it is unnecessary to disturb the patient to remove stitches

Present Condition of the Aseptic Treatment of Wounds

Mr Burghard, London, used the term "aseptic" to embrace all the measures adopted to keep the wound free from the ill effects of septic micro organisms as distinguished from the term antiseptic, which implied that sepsis was already in existence For the sterilizing of instruments the simplest method is boiling, but, half an hour should be allowed in order to certainly destroy spore bearing organisms A disadvantage is that it damages sharp instruments Sterilization by superheated steam is efficient if properly carried out, but without care is liable to fail Mr Burghard, therefore, rejects it Chemical antiseptics are useful for the disinfection of wounds, but must be used in weak solutions, otherwise they damage the tissues With regard to the surgeon's hands, experiments show that simple washing will remove many organisms, but is not to be relied on The results, however, are good when reinforced by saturating the skin with antiseptics for a fairly long period Sterilized gloves are open to many objections With them it is difficult to perform delicate manipulations, and there are many chances of damaging the gloves and bringing the unsterilized hand in contact with the wound The use of rubber gloves should be confined to virulently septic cases, where the surgeon is doubtful whether he can prevent his hands from carrying infection to the next case At King's College Hospital Professor Watson Cheyne and Mr Burghard boil all instruments except the sharp steel ones for half an hour, the latter are plunged into liquefied carbolic acid for five minutes, so, also, are all instruments required during an operation, which have not been sterilized beforehand Ligatures of chromic cat gut are soaked in a 1 in 20 carbolic solution for at least a week Silk and silkworm gut are sterilized by first boiling and then being kept in 1 in 20 carbolic acid Instruments, ligatures and sutures are dipped in 1 in 2,000 corrosive sublimate solution to wash off the carbolic acid The hands are freed from grease by turpentine, followed by prolonged washing with pumice stone, nail brush, soap and hot running water, and are then immersed in a 1 in 20 carbolic solution with 1 in 500 corrosive sublimate, which is afterward washed off in a 1 in 2,000 sublimate solution The patient's skin is prepared in a similar way (if possible, some hours before operation) and then covered with an antiseptic gauze dressing, and the cleansing is repeated on the operating table The field of operation is surrounded with boiled towels which have been immersed in a hot 1 in 2,000 lotion Marine sponges are used They are kept in a jar in a 1 in 20 carbolic solution They are taken out with forceps and dropped into a 1 in 2 000 sublimate solution During the operation they are frequently squeezed out of this solution to free from blood The operator and his assistants frequently rinse their hands in this solution After closing the wound double cyanid gauze wet with 1 in 4,000 sublimate, is applied

DISCUSSION

In the discussion which followed many other methods were mentioned

Mr. Stiles, Edinburgh, insisted that the great danger of infection lay in its conveyance by contact from case to case by the surgeon

Early Diagnosis and Radical Operation for Mammary Cancer

Dr. W L Rodman, Philadelphia, read a paper on the Early Diagnosis and Radical Operation for Mammary Cancer The following were his conclusions 1 Cancer is not only increasing in frequency, but it is also occurring more frequently in young subjects and has become common in races once immune 2 In young subjects the prognosis is less favorable, as the lymphatics are more numerous and potent than in the aged, in whom many are atrophied 3 An early diagnosis should be made, and no time lost in waiting for an operation, as metastases to the axillary glands and internal organs occurs early 4 When in doubt as to malignancy, a complete operation should be arranged for, but before removal of the breast an exploratory incision should be made into the growth and a piece from near its center examined by a pathologist (who can report in 10 minutes) If malignant, a complete operation should be done at once In women past 40 the chances in favor of malignancy are as 13 to 1, and should, therefore, be assumed 5 Carcinoma of the sternal is less common than in the axillary hemisphere, but probably more frequent than is generally supposed The prognosis is worse than in cancer of the axillary hemisphere 6 Recurrence being usually in the skin, its removal can not be too free Skin grafting or closure of the wound by plastic flaps (the preferable method) will frequently be necessary 7 Both pectoral muscles should be always removed, regardless of infection, so that all diseased tissue can be removed at one piece and the axillary dissection both more thoroughly and safely made Their loss does not increase the mortality, lengthen the convalescence or impair the subsequent usefulness of the arm 8 The supraclavicular glands should be removed if palpably enlarged, or if the topmost axillary glands show macroscopic involvement, otherwise their removal is unnecessary 9 Wounds of the axillary vessels have been infrequent since the muscles have been removed as a routine process 10 Drainage should always be made. 11 The 3 year limit of Vallsmann is insufficient and should be extended to at least 5 years Recurrence may take place after 10 or more years 12 Radical operation, if performed early, should give more than 50 per cent. of cures

Hepatic Drainage

Dr. John B Deaver, Philadelphia, read a paper on "Hepatic Drainage" The following were his conclusions 1 The mortality of biliary tract surgery is proportionate to the extent of the complications 2 Lesions of the liver, gall bladder and their ducts are the result of an infection usually persisting up to the time of operation 3 The salvation of infectious cases lies in prolonged drainage of the bile 4 Cholecystostomy is the operation of choice in such cases, and cholecystectomy only to be resorted to when changes in the gall bladder require its excision 5 Hepaticus or choledochus drainage should not be considered if cholecystostomy is feasible, unless it be necessary to open the common or hepatic ducts for the extraction of a stone 6 Early diagnosis and prompt operation are essential for a low mortality, where gallstones are present or not

(To be continued)

CALIFORNIA ACADEMY OF MEDICINE

Meeting held at San Francisco, July 26, 1904

The President, Dr T W Huntington, in the chair

Studies on a Salt-Free Diet.

Dr. A E Taylor described the results of a salt free diet on metabolism The question has a great clinical interest on account of the recent observation of Widal that in certain cases of nephritis a diminution in the amount of chlorids ingested will dispel the edema Dr Taylor placed himself on a diet consisting of 70 gm of egg albumin, 120 gm of olive oil and 200 gm. of cane sugar daily Such a diet will yield about 2,300 calories daily and contains only about 100 mg of salts During the first day of the experiment, 2,000 c c of urine were passed, during the second, 1,900 c c After the third day the amount fell to normal and remained there Diaphoresis was a more marked symptom than diuresis Although the weather was cold, he was in a continual state of perspiration On the fifth day general muscular soreness was experienced, and later the muscles became very painful On the eighth and ninth days muscular twitchings developed The reflexes remained normal On the ninth day acetone and diacetic acid were discovered in the urine, and the experiment was terminated

The urine was increased only during the first few days Its reaction remained remarkably constant. The amount of salts gradually diminished and approached a minimum constant The indican and the paired sulphates gradually increased On the last day the ammonia increased very much owing to the acidosis The gastric analysis and the saliva were apparently normal

The presence of acetone and diacetic acid in the urine in this experiment is difficult of explanation There seems to be no connection with the ordinary causes of acidosis, viz, starvation, excessive fat or meat diet, or diabetes

Three or four pounds weight were lost during the experiment apparently mostly water, since it was rapidly recovered in the next few days

Renal Lesions with Misleading Symptoms

Dr. L. W Allen reported two cases of renal disease in which misleading symptoms were present The first was a healthy looking, well nourished woman, who complained of a tumor in the right side and some discomfort in this region Examination showed some enlargement of the right kidney There was no fever, and the urine showed only a faint trace of albumin The kidney showed at operation very advanced tuberculosis

The second patient suffered from sweats and irregular fever, and was extremely emaciated The right kidney was enlarged and very tender Leucocytes were 6,000 The urine, especially that from the right kidney, contained a large amount of pus, and cultures showed colon bacilli No tubercle bacilli were found Nevertheless, renal tuberculosis seemed the probable diagnosis on account of the general condition of the patient At operation no abscesses were found in the kidney There was a pyelitis from which colon bacilli in pure culture were obtained Complete recovery took place The patient had evidently suffered from a chronic sepsis as the result of a colon bacillus infection

DISCUSSION

Dr. Ophüls said that in regard to the first case it is not unusual for a ureter to become blocked in renal tuberculosis so that urinary examinations fail to show any abnormality In regard to the second case, chronic septic conditions seem to be much more common than is generally supposed For example, he had recently observed *a number of cases of malignant* endocarditis *of* two and three years standing, caused by an organism of low virulence Such cases are clinically usually mistaken for non malignant endocarditis

Intermittent Claudication

Dr P K **Brown** has recently seen two cases of this disease, and in this connection spoke of Erb's[1] recent paper

Dr A W **Hewlett** reported a case of a man of 67 years who suffered from pains and sensations of cold in his feet whenever he walked After walking about a block these sensations would appear, and he would be compelled to stop and rest. After five or ten minutes his legs felt normal, and he could again walk with comfort There was no pulsation in the arteries about his feet, which were cold and pale, except for a bluish area *on the ball of the great toe* Later the patient developed cardiac insufficiency from an associated myocarditis, and since he has been in bed the symptoms of coldness and pain in the feet have disappeared

Dr R **Cabot** stated that he had seen two cases of intermittant pains in the abdomen possibly due to arteriosclerosis of the splanchnic vessels Without autopsy however no positive diagnosis could be made In regard to the influence of alcohol as a causative factor in the production of arteriosclerosis, he has made a series of observations on alcoholics which would seem to show that the excessive use of alcohol alone does not produce arteriosclerosis

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns The writer's name must be attached, but it will be published or omitted as he may prefer It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in everyday practice Proper inquiries concerning general formulae and outlines of treatment are answered in *these columns* without allusion to inquirer]

Hay Fever

Fick, in the *Therapeutische Monatshefte*, discusses the treatment of this condition with the Dunbar antitoxin and concludes that this antitoxin, which, according to Dunbar, produces a short lived immunity, does not and can not have any action at all In the second part of the paper *he gives* his own theory of the etiology of hay fever and his method of treatment The attacks are directly caused by *some irritant* agent, of which grass pollen is the most common The writer denies that the nasal symptoms are due *to vasomotor* disturbances, and shows that irritation of the nerve endings of the trigeminal causes a hypersecretion *This hypersecretion* is localized in the antrum of Highmore, and the fluid finds its way into the nasal fossa naturally The author states that he has found aristol to cure *all forms of nervous coryza*, including hay fever *He passes a canula*, which is very thin *and curved* in correspondence to the lower turbinated bone, into the maxillary antrum *in about 95 per cent of all the cases* Through this canula he blows the aristol powder into the antrum As a rule this need *only be repeated* every day for three days, after which the attacks become less frequent and milder When they recur the *insufflation* is repeated

Furuncles.

Gallois and Courcoux, in *La Presse Medicale*, recommends the following solution to be used in the abortive treatment of furuncles

℞	Iodin	ʒi	4
	Aceton	ʒiiss	10

M Sig Use locally by saturating an applicator carrying cotton and touching the nodules

Lesions which have not suppurated and even those which contain a drop or two of pus superficially, are aborted within twenty four hours

The solution is more caustic than the tincture, and must be used with greater care In an open wound it causes severe pain and may produce symptoms of iodism

Hyperhidrosis.

Excessive perspiration is a comparatively frequent and rather disagreeable condition The *most common localities* are the palms, soles, axillæ or genitals Kaposi recommends the following

℞	B naphthol	ʒiiss	10
	Spiritus colon	ʒiv	16
	Spiritus vini	℥vi	180

M Sig Use as a wash, or

℞	Naphthol	gr lxxv	5
	Glycerini	ʒiiss	10
	Alcoholis	℥iiiss	105

M Sig Wash feet night and morning with this mixture, dry, and then dust with this powder

℞	Naphthol	ʒss	2
	Amyli	℥vi	180

M Sig Use as dusting powder

The following is recommended to dust into the shoes each morning

℞	Pulv talc	ʒx	40
	Bismuthi subnitratis	℥iss	45
	Potassii perman	gr xlv	3
	Sodii salicylatis	gr xxx	2

Or, bathe the feet once daily *in* hot water, *dry*, and the following *may* be used as a dusting powder

℞	Acidi salicylici	gr lxxv	5
	Pulv alum	ʒiiss	10
	Pulv amyli	ʒx	40
	Pulv talc	℥ivss	135
	Alcoholis	ʒiiss	10
	Olei bergamot q s to perfume		

Chronic Rheumatism

Merck's Archives recommends the following

℞	Sodii iodidi	ʒii	8
	Vini colchici rad	ʒiv	16
	Sodii salicylatis	ʒiii	12
	Tr guaiaci ammon	℥ii	60
	Syr sarsaparillæ comp q s ad	℥vi	180

M Sig Dessertspoonful three times daily

The *Med Record* recommends for this condition

℞	Pulv guaiaci resinæ		
	Potassii iodidi, āā	ʒi	4
	Tr colchici seminis	ʒiii	12
	Syrupi simplici	℥ii	60
	Aquæ cinnamomi q s ad	℥vi	180

M *Sig* Dessertspoonful to a tablespoonful twice daily

Markly, in the *Med Summary*, advises that the patients eat less, bathe oftener and keep the skin active, drink a great deal of water, keep out of draughts and avoid colds, keep the bowels active, urine neutral or slightly alkaline, and take a course of iron three or four times a year The patient should also take colchicin in ascending doses until he has at least two good stools daily, then continue that dose a long time

Muscular Rheumatism

The salicylates are seldom of much benefit Gentle rubbing and mild counter irritation are always indicated The following formula has given great satisfaction in French hospitals

℞	Spiritus camphoræ		
	Spiritus terebinthinæ āā	℥iss	45
	Chloroformi	ʒii	8
	Mentholi	ʒi	4
	Balsami Peruvi	℥iss	45

M Sig Apply with gentle friction

Cholera Infantum

Wallace discusses this disease in the *Virginia Med Semi Monthly*, and outlines *the following method of treatment* which has been successful in his hands. Depression gives the keynote to the treatment, namely, stimulation. Each case is individual, but bold and early use of whiskey or brandy should be used in every case where the stomach will tolerate it. Give the stimulant freely, for alcohol will not poison half so quickly as the toxins in the blood.

---

[1] The Journal A M A, p 203

The nausea and diarrhea he treats with heroic doses of calomel, one fourth of a grain every hour if the child is over six months old, continue until signs of bile in the stool or until three grains are taken. After the bile appears in the stool he gives a big dose of castor oil with a moderate dose of paregoric. The intestinal canal is kept clean by the administration preferably of bismuth subnitrate, which is usually well borne by the stomach, and is a simple and safe remedy. The sulfocarbolates and protan (Mulford's) may be used when the bismuth is not enough.

For diet rice water or albumin water are given: both leave very little detritus. The rice water is made as follows: two heaping tablespoonfuls of rice to two quarts of water, boil for three hours, adding water to keep up to two quarts.

The patient should be kept in bed. Tepid sponge baths should be given for the temperature.

Acute Infantile Diarrhea

Merck's Archives recommends the following:

℞	Tannalbin		
	Spiritus vini gal., aa	ʒii	8
	Syrupi simplicis	ʒiv	16
	Aquæ destil. q. s. ad	℥ii	60

M. Sig. Tablespoonful four to six times a day.

Hyperpyrexia in Scarlet Fever and Measles.

Berg, in the *Med. Record*, discusses the temperature in these two diseases, and gives the following as his method of treating the hyperpyrexia.

The patient is placed in a bath with the water at a temperature of 80 F., at the end of from five to ten minutes, depending on the case, the temperature of the water is raised to 90 F. by the addition of warm water. A bath at the temperature of 80 F. is a cooling bath to a patient with a temperature of 105 F., yet not cool enough to produce any evil effects on the capillaries. The subsequent raising of the temperature of the water has the effect of giving a warm bath after the cool one. Whatever ill effect may have been produced by the bath at the temperature of 80 F. is more than counterbalanced by the bath at 90 F., and still it is much lower than the temperature of the skin. The patient is taken from the bath and wrapped lightly in a sheet and covered by a thin blanket.

Caution. When warm water is added it must be poured into the bottom of the bath tub. The reason for this is that if the warm water is poured on the top it floats over the cool water, unless mingled mechanically by the nurse. For this purpose the author has used a tin funnel with a rubber hose long enough to reach the bottom of the tub.

The warm water is delivered through this tube and rises because of its lightness and is disseminated through the bath. The patient should not be rubbed after such a bath, because the warm additional water accomplishes all or more than the rubbing in the Brand bath and the friction is detrimental to the inflamed skin.

The temperature will be found to have declined from one and one half to three or more degrees, and the decline persists longer than any other methods I have tried in these diseases. Moreover, the eruption is not diminished, the pulse is improved, sleep generally induced, and a gentle perspiration covers the whole body.

Lesser degrees of temperature are treated with sponging with water at 70 F., to which one third of ordinary alcohol has been added. The alcohol acts the part of the added warm water in the bath and counteracts the ill effects of the cool sponging on the capillaries and nerve endings in the skin. Do not use friction. Use a large soft sponge, the excess of water should be absorbed by patting the skin with a soft towel, and the patient lightly covered as after the bath.

Obesity

Grocco, in the *Rivista Critica di Clinica Medica*, gives the following rules for the treatment of obesity. The cause must be ascertained if possible, and then regulate the income and outgo so that they will be equalized. He considers the condition to be the result of an excess of the ingesta or of a derangement of the metabolism of the body. Reduce the amount of liquids taken at meals, and allow the liquids to be taken two hours after meals. In cases in which the urine is habitually concentrated and has deposits of urates or uric acid, a dry diet is not well borne. In such cases it is best to allow frequent small meals, four or five in the twenty four hours, with liquids taken two hours after meals. The diet is reduced until the weight of the patient falls to the desired figure, and then kept at the requisite amount to maintain a normal weight and prevent a renewed increase. There should be a great increase in muscular activity by walking, riding, cycling, sports or gymnastics. General and local massage when the abdomen is enlarged, is very useful. Hydrotherapeutic measures as well as carbonic acid gas baths are important. Patients should sleep moderately and not do excessive mental work. The author recommends the use of purgatives, alkalies, etc., only as they are indicated.

Medicolegal.

Rights of Sick Child with Relation to Its Custody.—The Supreme Court of Louisiana holds, in the case of State vs. Jones, where a father sought by habeas corpus proceedings to recover the custody of a child that was about two and a half years of age, weak and sickly from its birth, and which had always been taken care of by its grandmother, that, regarding the family and the right of the father, there remained authority enough in the courts to protect the health and life of the motherless, small, sickly child, by decreeing that it remain with its grandmother, to be taken care of and to receive needful nursing. It says that it might be that, under a very strict and even severe interpretation of the law, a decree should issue authorizing the father to take his child from the care of the grandmother. But that interpretation, in view of the (uncontradicted) testimony of the physician who had attended to the child from its earliest infancy, and who had testified that it would not be safe to take it away from its grandmother, would, to say the least, be hard on the child. The child, under Nature's laws, has some rights, not always to be overlooked. The parent's will is not always supreme. There may a case arise where exceptional parents take it out of the grasp of the law here invoked. The law does not interpose with an iron hand to sever a union essential at the time to the very life of the child. The law should be loved, rather than feared and to this end there are cases in which equity is not to be denied all hearing.

Valid Provision for Contagious Disease Hospital.—The Supreme Judicial Court of Massachusetts holds constitutional, in the case of Manning vs. Bruce, a statute providing that the city of Everett, by its City Council, may take any lands within the limits of the city for the erection of a hospital for the care of persons suffering from contagious diseases. It says that while so far as the statute affects the owner of property taken it is an act in the exercise of the right of eminent domain, it is, nevertheless, in the object ultimately to be reached, an act in the interest of the public health, and, so far as it confers the right to erect and maintain on the land taken a hospital for contagious diseases, it finds its sanction in the general police power subject to the proper exercise of which all property is held. It was not necessary to discuss the right to deal with contagious diseases. Even the right of personal liberty must yield to the measures necessary for the protection of the general health. A man afflicted with smallpox or any other contagious disease dangerous to public health has for the time being lost his right of personal freedom and may be compelled to yield to restraint, carried if necessary even to compulsory isolation. Hospitals must be established and maintained for such persons, and for more than a century cities and towns have been authorized by statute to do this, and, in case of the breaking out of a contagious disease dangerous to the public health, it is made the duty of the proper public officer to provide a hospital or place of reception Such laws, being necessary for the protection of the public health, are wholesome and reasonable, within the meaning of the phrase as used in the constitution, and they violate no constitutional provision Under the general law the city could have erected such a hospital, but it was limited to such land as it could buy, and no doubt this statute was passed not so much to grant it authority to build and maintain a hospital as to enable it to obtain, by the exercise of the right of eminent domain, a site for it Such a hospital is under the supervision of the board of health, and it is not to be assumed in advance that it will be a nuisance, public or private

Rules Applicable to Trials on Question of Insanity—The Supreme Court of Alabama states, in Parrish vs State, a *homicide case, the rules of law applicable to trials on the* question of insanity as follows It is now well settled law and practice that, as to the question of whether insanity exists or not, witnesses, whether expert or non expert, may express their opinions as to the sanity or insanity of a defendant on trial for crime Ford's Case, 71 Ala 385, and other Alabama cases The witness, whether expert or not, must first be shown to be competent or qualified to give an opinion as to the sanity or insanity of the party inquired of The question as to the competency of the witness, whether expert or not, to give an opinion as to the sanity or insanity of the party inquired of, is *a question for the court and not for the jury As to this* question, its decision as to competency will not be revised unless it clearly appears to have been erroneous People vs McCarthy, 115 Cal 255, note on page 733, 38 L R A An expert witness may give an opinion as to the sanity or insanity of an individual, based solely on a hypothetical question, without any personal knowledge or acquaintance with the individual inquired of Gunter vs State, 83 Ala 96, Burt vs State (Tex), 40 S W 1,000, 43 S W 344, 39 L R A 305, and note A non expert can not give an opinion as to the sanity or insanity of the individual inquired of, based in whole or in part on an abstract hypothetical question, but must base his opinion solely on his own personal knowledge, observation, acquaintance, experience, etc, with the individual inquired of Roberts vs Trawick, 13 Ala 68, Burney vs Torrey, 100 Ala 157 Non expert witnesses, to give an opinion as to insanity of a party, must first state the facts claimed to show or indicate an abnormal condition of the mind, but such a witness may give an opinion that the person inquired of was sane by first merely denying generally the existence of any facts showing an abnormal or unnatural state of mind, and without specifying any of such facts Caddell vs State, 129 Ala 65 The hypothetical question propounded to an expert witness should embrace substantially all the facts, where there is no dispute as to the facts on the question of insanity Davis vs State, 35 Ind 496, Webb vs State, 9 Tex App 490, State vs Barber 74 Mo 292 Goodwin vs State, 96 Ind 554 If the evidence is in conflict as to the facts tending to show insanity, the hypothetical question may and should properly embrace only the facts tending to support the particular theory of the respective party, and the opposing party, if desirable, on cross examination of the witness, may propound questions to him embracing the facts which tend to support his theory Grubb vs *State, 117 Ind 277, People vs Hill*, 116 Cal 562 The hypothetical question to an expert witness should not contain matter as to which there is no evidence tending to support However, technical accuracy is not required as to this It is for the jury to scrutinize the evidence and to determine what part of the question is true, or supported by the evidence, and what is not and the adverse party may ask for instructions that the jury do not accept the facts as true but that they should determine whether such facts were in evidence, and that they might disregard the opinion of the expert if not based on facts in evidence Grand Lodge vs Wieting, 168 Ill 408, Forsyth vs Doolittle, 120 U S 76 Expert witnesses may be cross examined and their opinion obtained, based on other states of facts, assumed by the party examining them to have been proven on a hypothetical case, and they may be cross examined on purely imaginary and abstract questions Such questions are not only permissible in order to get the opinion of the expert witness on all the possible theories of the case, but they are allowable also to test the value and accuracy of *the opinion of the witness himself* Clark vs State, 12 Ohio, 483, People vs Sutton, 73 Cal 243 The opinions of expert witnesses as to insanity are not conclusive on the jury They are to be weighed like other evidence Such evidence is intended to aid the jury, and its value depends largely on the intelligence, experience, honesty and impartiality of the witnesses, and their opportunity of knowing the traits and habits of the person whose mind is under investigation Its weight is solely a question for the jury They may reject it all, though it is without conflict McAllister vs State, 17 Ala 434, Williams vs State, 50 Ark 511, People vs Barberi, 47 N Y *Supp* 168 *Insanity can not be proven by reputation*, notoriety or hearsay Kimbrell vs State, 130 Ala 40, 44, 16 Am & Eng Ency of Law (2d Ed) 612 In the trial of a homicide case, where the statutory plea of not guilty by reason of insanity is interposed, the burden of proof is on the defendant to establish the plea to the reasonable satisfaction of the jury by a preponderance of the evidence, and a reasonable doubt is not sufficient to acquit the defendant under this plea

1 —See abstract in The Journal, xlii, p 1584

4 **Myelogenous Leukemia** —Evans presents a history of three cases of myelogenous leukemia, and calls attention to the treatment which is being used in two of them These two patients were exposed to Rontgen rays emanating from a medium high vacuum tube at an average distance of ten inches for from fifteen to twenty minutes daily A steady and progressive diminution in the size of the spleen was noticeable from the first One of the patients received 125 treatments, averaging 17½ minutes for each exposure There were four intervals when treatment was suspended for ten, two, five and seven days respectively Aside from a slight reddening of the skin over the exposed part on a few occasions, nothing but the characteristic bronzing was noticed At one time there was a decided increase, both relative and actual, in leucocytes, especially the myelocytes, together with an increase in the size of the spleen Just preceding the time this was noticed a number of exposures had been made with a tube of a lower vacuum and consequently producing rays of less penetration As soon as this error was corrected the patient resumed her previous condition Her last blood count showed 3 680,000 red cells, leucocytes 88,000, hemoglobin 70 per cent. The proportions of the various kinds of leucocytes were about normal The second case received in all 61 treatments After the thirty sixth treatment the spleen disappeared beneath the costal margin, and by the forty fifth treatment was normal in size and position The general condition of the patient was excellent The last blood count showed 3 600,000 red cells, leucocytes 12 600, hemoglobin 80 per cent The proportion of leucocytes was about normal, but as in the previous case, a large number of myelocytes, 12 and 21 per cent respectively, were found Speaking of the histogenesis of leucocytes, Evans says that the large mononuclear leucocyte is the mother cell, *ordinarily* capable of further

differentiation into either the ordinary basophilic cell or into a neutrophilic myelocyte The two forms of leukemia, lymphatic and myelogenous, are closely associated, and, perhaps, are forms or stages of the same disease The lymphocytes, he thinks are formed in the lymphoid tissue of the bone marrow, and the myelocytes, which also are formed in the bone marrow are the parent cells of the polymorphonuclear neutrophiles In myelogenous leukemia, myelocytes are cast into the circulation probably because of the increased activity of the myeloid tissue of the marrow, the only tissue primarily affected in this disease

5 **Acute Suppurative Pancreatitis**—Porter describes a case of acute suppurative pancreatitis in which death followed sixty six hours after the onset of the illness The diagnosis rested between pancreatitis, ruptured ectopic gestation obstruction of the vessels of the mesentery and obstruction of the bowels It was finally concluded that a positive diagnosis was not possible, and that the probabilities were in favor of a ruptured tubal pregnancy Porter advised immediate operation but other consultants in the case did not agree with him and no operation was performed Postmortem examination revealed the abdomen bathed in pus The head of the pancreas was about one half destroyed The uterus and appendages the spleen and other abdominal viscera were normal In favor of the diagnosis of ruptured tubal pregnancy were the history of the miscarriage, of pain and tenderness in the pelvis, together with the fact that at the onset the pain was greatest in the pelvis Four or five weeks prior to the last illness the patient had been having boils, and it is highly probable that the infection was carried to the pancreas by the blood stream from one of the boils Unquestionably many of these patients will die even when operated on early, but the operation will not kill them and gives the best chance for recovery in all cases in fact the only one in most cases

7 Report of a Case of Ruptured Ectopic Gestation John W Coe
8 Some Interesting Obstetric Experiences. J J Gurney Williams
9 *Chronic Mastitis and Diffuse Fibroadenoma of Breast D Farquhar Curtis and F C Wood
10 Hereditary Syphilis Howard S Kinne
11 *Difficult Cases of Infant Feeding T W Kilmer
12 Transitions of Obsessions to Delusions Report of Two Cases Alfred Gordon
13 *Moot Points in the Treatment of Fractures Martin W Ware

9 **Chronic Mastitis**—Curtis and Wood review chronic mastitis and diffuse fibroadenoma of breast, two conditions which can only be distinguished by careful microscopic examination, the diagnosis, therefore, being impossible before their removal They are so frequently followed by the development of cancer that they can be considered preliminary stages of that dangerous neoplasm Up to the present time there is no absolutely reliable sign to distinguish between these two conditions and carcinoma before one of the cardinal signs of malignancy makes its appearance The surgeon should not wait for any further development after having made the diagnosis and action should be taken at once With reference to the treatment these cases can be divided into three classes 1 Moderate induration limited or general 2 Marked induration, limited to one quarter of the breast or less 3 Marked induration general Curtis reports a number of cases in point, and the article is closed by Wood with a discussion of the pathology of these breast indurations

11 **Infant Feeding**—Kilmer discusses the necessity of feeding each infant in accordance with the demands of its growth and the capabilities of its digestive system Large, fat, apparently healthy looking babies are not always such Too much carbohydrates, fats and proteids will fatten up a baby wonderfully, but ere long the crash comes, and then the real trouble begins The author styles condensed milk as "one of the worst curses on a community of babies" Still he goes on to say, it is unquestionably one of the best foods to switch off on if baby's stomach becomes a little upset from too much proteid Often it helps to tide many a baby over a critical heated period The artificial feeding of babies is not the simple and easy problem which some seem to regard it Every baby is a law unto itself and should be fed as an individual The general public should be taught that they should not and can not feed the rising generation on "any old thing" and in any way they choose

13 **The Treatment of Fractures.**—Ware gives the results of his study of 3,000 cases of fractures, commenting on the methods of diagnosis and the apparatus to be used in treatment, the best of which, he says, are the simplest materials, such as plaster of paris, pasteboard, cigar box wood and non absorbable cotton A number of illustrative cases are cited, but the author presents nothing new

16 *Subperiosteal Fractures of the Humerus in Children J S Stone
17 The Physical Relationship of Finsen Light Roentgen Rays and Radioactivity W C Sabine

15 **Malpositions of the Uterus.**—Brown believes that the uterus remains in its normal position by the concerted action of its several ligaments and the pelvic fascia, which are mutually interdependent for their integrity and action He does not believe that the perineum is responsible for the support of the uterus and vagina He discusses the causes of retrodeviation, both in virgins and in parous women, and follows Krusen's classification The symptoms and treatment of the various malpositions are considered in brief For the treatment of laxity of the uterosacral ligaments, Brown believes the Goelet operation to be a step in the right direction In anteflexion the Dudley operation is the best Excessive mobility of the uterus may be overcome by the wearing of a pessary of a cervicovaginal fixation For prolapse and procidentia he favors the Byford operation When a hysterectomy is decided on the vaginal route is preferable, uniting the anterior and posterior peritoneal margins, and then an end to-end approximation of the stumps of the broad ligaments forms a perfect support

16 **Subperiosteal Fractures of the Humerus in Children.**—Stone describes five cases which illustrate the dangers of overlooking fractures in children, and calls particular attention to the symptoms by which subperiosteal fractures of the surgical neck of the humerus may be diagnosed in the absence of the usual signs of fracture When, after a fall on the arm or shoulder, children are unable to abduct the arm, but present none of the other signs of fracture or dislocation, and are able to move the arm in other directions, most careful examination should be made to determine localized tenderness anteriorly just below the head of the humerus, together with a slight irregularity in the contour of the bone at the same point These signs are sufficient to establish a diagnosis of fracture of the surgical neck and further attempts by rough handling to secure crepitus or mobility should be deterred from

21 *Acute Cholecystitis Simulating Appendicitis Arthur L Chute
22 Treatment of Syphilis by Hypodermic Injection of Mercury Lawrence T Royster
23 *A New Pathogenic Throat Organism B H Stone

18 **Physical Remedies in Pulmonary Phthisis.**—Baruch summarizes his views on the subject of phthisis therapy in general, and points out that phthisis may be regarded as an illustration of what can be acomplished by systematic methodical management in all chronic diseases Constant, unremitting attention to every detail of the patient's mode of life, his environment food, drink, rest, exercise, baths, clothing and occupation is the only road to a favorable result Hydrotherapy as applied to the treatment of consumption is discussed in full

The indications are, 1, to increase blood cells and hematosis, 2, to deepen respiration, 3, to enhance nutrition, 4, to eliminate excretory products, 5, to remove stasis, 6, to reduce temperature Success in the use of hydrotherapeutic measures is dependent on a full and thorough knowledge of their application The most useful general method is the one which aids in gradually accustoming the skin to lower temperature, greater pressure on mechanical force, and larger quantities of water—in all stages In febrile cases low temperature applications are contraindicated. Here the ablution or a half bath, with water not below 80, is indicated The author's method is as follows

> After a thorough cleansing with soap and warm water, a day is allowed to elapse The patient is wrapped snugly in a thin blanket like a mummy (unless rectal temperature is above 100) He is allowed to lie for half an hour or longer unless he perspires In afebrile cases it may be necessary to cover with additional blankets the object being to fill the cutaneous arterioles preparatory to being treated with water The face is bathed with water at 50 F Now the blanket is opened over the chest and abdomen and these parts are rapidly and well rubbed with water at 75 F After drying the patient is turned on the abdomen and the back is similarly treated The extremities are not treated Patient is gently dried dressed and if afebrile ordered into the open air for a gentle walk Febrile cases are returned to bed This treatment is repeated daily with reduction of two degrees of water temperature at each ablution until 60 F are reached Now the ablution is performed just as the patient emerges warm from the bed, as follows Standing in a foot tub containing sufficient water at 100 F to cover the feet to the malleoli he receives a rapid friction bath with water at 90 omitting the upper extremities, after which he is dried and sent into the open air if his rectal temperature is below 100 F The water temperature is reduced daily two or five degrees until 60 F are reached Now the ablution is replaced by affusion which consists of pouring of four basinfuls of water at 90 F, previously held in readiness, over the body The patient standing in a foot tub having his feet covered with water at 100 water is dipped from a vessel previously in readiness and poured with force over each shoulder and back and chest Rapid drying while standing on a warm towel completes the procedure Beginning with a water temperature at 90, it is daily reduced a few degrees until 60 or even 50 are reached This refreshing process may be repeated daily In febrile cases the water temperature should not go below 65

20 **Associated Movements of the Upper Eyelid and Lower Jaw**—Coburn discusses this subject reports a case and reviews the literature The relationship of this condition to chronic nuclear palsy is suggested by the following facts 1 This condition is not always congenital, cases have been reported in which it appeared somewhat late in life 2 This disease is not always stationary, in some it has increased, in others diminished 3 Although usually unilateral, it is sometimes double, especially the ptosis 4 The lack of development of the face in some cases points to trophic disturbances in the seventh nerve, a condition often accompanying the infantile form of nuclear palsy There seems to be very little that can be done to relieve this condition Operations for ptosis have been performed successfuly on these cases, and there seems to be no objection to them as long as the operation is not so radical as to cause permanent exposure of the eyeball

21 **Acute Cholecystitis Simulating Appendicitis.**—Chute reports two cases of this kind, and says that the greater number of instances are seen in that group of cases in which the inflamed gall bladder is in its normal position, but in which pain and tenderness, in the presence of distention and rigidity, are referred to the appendix region The second group of cases is made up of those cases in which an inflamed gall bladder reaches into the iliac fossa, either through great enlargement or through displacements Here the error in diagnosis is the result of finding a painful tender mass in the region of the appendix This type is less common than the first Both of the author's cases belonged to the first type In dealing with supposed cases of either of these two most common intra abdominal inflammations, one should always bear in mind the closeness with which they may simulate each other When, during an operation, the state of the organ investigated does not satisfactorily account for the patient's condition, the other organ should always be examined The lack of this precaution has, in at least one recorded case, led to the removal of a slightly diseased appendix, while, as the autopsy showed, the symptoms had been caused by a gangrenous gall bladder which had not been discovered

23 **New Pathogenic Throat Organism**—Stone made a bacteriologic study of 81 cases of an acute inflammatory condition of the throat, accompanied by a severe but not fatal toxemia, lasting from twenty four to forty eight hours The cases are usually ushered in with chilliness, pain in the head and limbs, and a coryza, often accompanied by an unusal amount of sneezing In nearly all of these cases the tonsils were more or less swollen, the soft palate and uvula edematous, and in many there has been a distinct false membrane, white in color and very tenacious These cases have been diagnosed as diphtheria, grippe and simple cold The remarkable fact about these cases has been the severe toxemia coming on suddenly and lasting only a short time, and the universal appearance in the throat of a peculiar diplococcus The same organism has been met with in several cases of typical follicular tonsillitis and in the throats of three cases of scarlet fever and in many cases of irritable throats following diphtheria The organism occurs in the secretions and exudations of the inflamed mucous membrane It is a diplococcus with its adjacent sides slightly flattened One of the pair often is smaller than the other They vary from one half to one micron in diameter They stain redly with Loeffler's stain and fuchsin, and by Gram's method, and show polar granules with the first stain only They possess no flagella, spores or demonstrable capsule. Almost no growth occurs in gelatin, and there is no liquefaction On agar plates small, white, raised and very tenacious colonies appear after twenty four hours incubation. The growth on agar streak cultures is the same, except that the colonies coalesce along the line of the needle tract, and the result is a more or less continuous nodular growth On blood serum the growth is luxuriant, forming a viscid, extremely tenacious skin over the whole surface of the medium The growth on potato is similar to this, only less luxuriant In boullion it forms a white, stringy sediment, sticking slightly to the bottom of the tube It does not change the reaction of the media, does not form indol or gas or acid in glucose, lactose or saccharose solution It converts nitrates into nitrites It is a facultative anerobe growing best at the body temperature, with a thermal death point between 60 and 70 C The writer is thoroughly convinced that this organism stands as the etiologic factor in the cases studied even though efforts to reproduce its peculiar lesions on the mucous membranes of laboratory animals thus far have been unsuccessful It has been found constantly present in these cases in almost pure cultures, and has been isolated, while no other organisms are constantly found It is toxic for laboratory animals, producing on scirrhus membrane an exudate analogous to that produced in the throat, from which exudate it has been recovered in pure culture It produces a soluble toxin sufficiently virulent to kill animals Its blood serum growth has a peculiar viscid character, suggesting the extreme viscidity of its exudate in the throat

28 *Is Milk a Factor in the Spread of Tuberculosis? J O Cobb
29 Morphinism Its Symptomatology Charles J Douglas
30 *Adenoids in Infants Herman Jarecky

24 **Aberrant Thyroid Tissue**—Ferguson discusses the relation of aberrant thyroid tissue to intratracheal growths, and describes one specimen which he had the opportunity of studying The literature on the subject is reviewed very carefully

26 **Suppression of Rotary Vertigo**—Corning presents the results of a series of experiments on individuals in whom vertigo had been induced artificially by means of a revolving chair invented by the author Various drugs were tried to prevent and to relieve the symptoms of the vertigo, but those of most value were found to be hyoscin and opium or morphin Hyoscin hydrobromid, in doses of 1/150 gr , and opium, in ½ gr doses, was found to be efficient Of course, the dose must be varied somewhat according to individual susceptibility These remedies produce a central as well as peripheral torpidity, so that the subject will remain proof against both giddiness and nausea for from three to four hours, when the administration of a tablet consisting of morphin, gr 1/6, extract of cannabis

indica, gr ¼, nitroglycerin, gr 1/300, strychnin sulphate, gr 1/60, resorcin, gr 1, cocain hydrochlorid, gr 1/6, was sufficient to produce further immunity for a like period This treatment was especially valuable in the prevention of sea sickness

28 **Milk and Tuberculosis**—Cobb reviews the data at hand with reference to milk being a factor in the spread of tuberculosis, and arrives at the conclusion that its etiologic importance is very much over estimated, because in those countries where milk is used but little or not at all, and in others where it is invariably boiled before using tuberculosis is as prevalent as in countries where milk is used largely

30 **Adenoids in Infants.**—Jarecky emphasizes the fact that adenoids exist in infants and that an early operation saves the patient from the defects caused by ignoring their presence In making a diagnosis of adenoids in infants we must naturally depend to a great extent on inability to nurse properly and noisy mouth breathing Five cases are cited and the usual method of treatment is described

38—This article has appeared elsewhere See THE JOURNAL of July 30, ¶55, p 354

39 **Osteotomy in Ankylosis of the Hip**—Mueller considers osteotomy as the most important step toward obtaining a definite result in angular ankylosis of the hip joint, provided, that the ends of the severed bone will knit together nicely and in the desired position To secure the first condition, it is necessary that no tissues become interposed between the ends of the bones, and calls for exact approximation The second point calls for securing this result and for excluding all changes of position due to muscular action or tension In all cases of distinct abduction ankylosis, subtrochanteric osteotomy is the operation of choice, and should be performed as high as possible In flexion ankylosis one group of flexors is tenotomized, while another group must be stretched, in adduction ankylosis the action of the adductors should be eliminated in a similar way The same operation ought to be applied to the muscles, acting as abductors in abduction ankylosis A cast properly applied in extension fixes the ends of the bone, severed by the osteotomy in an absolutely safe way without allowing any displacement, and also permits the patient to walk around within a few days after operation Mueller recommends the so called "circumference chisel" designed by Reiner, which is especially constructed for the purpose of osteotomizing the distal end of the femur in genu valgum, as the most useful instrument for the performance of osteotomy He uses an instrument which is a simplification of Reiner's chisel It is shaped like a chisel with an oblique edge, having a protruding thorn on the shorter side. If the unprotected edge of the chisel is placed on the bone, a few strokes with the mallet will drive it in until the thorn stops its deeper intrusion All further strokes drive the osteotome over the circumference of the bone Severing the corticalis until only a narrow bridge is left, this and the rest of the spongy substance is very easily broken, and the rough surfaces of this artificial fracture act as a means of preventing dislocation of the ends of the bone Another advantage of this osteotome is the possibility of working with it beneath the periosteum The periosteum is divided by a longitudinal cut, and is lifted up by an elevatorium in both directions around the circumference of the bone Through this slit the osteotome is introduced, and after the osteotomy has been performed the wound in the bones is protected by a mantel of periosteum, preventing any interposition of other tissue Convenience and rapidity are the advantages which the circumference chisel possesses

46 *Earache F L Stillman
47 What May Be Accomplished by the Organized Profession Toward Improving the Ohio State Medical Institutions A. P Ohlmacher
48 The Relation of the Medical Practitioner to Preventive Measures Against Tuberculosis. Arthur Newsholme

45 **Differential Diagnosis of Chronic Skin Diseases**—Collins believes that the difficulty of diagnosing skin lesions is usually overestimated and is due more to the lack of systematic study of the case in hand than to the complexity of the symptoms presented The rarer conditions are encountered so seldom that they need hardly be considered by any but dermatologists In examining a case of disease of the skin special attention should be directed to four points 1 The particular region of the body over which the lesions are distributed 2 The arrangement of the lesions, as to whether they are regular or irregular, circular, bilateral, symmetrical, etc 3 The lesions themselves should be studied in detail and classified 4 The presence or absence of constitutional symptoms should be inquired into, and if present their nature noted The following points are of importance in arriving at a diagnosis Bilateral symmetrical eruptions are either constitutional in origin or are due to the same local causes on both sides of the body Diseases due to parasites are usually found on the flexor sides of the limbs or on the exposed parts of the body The more chronic the disease the deeper the color, and, *vice versa*, the more vivid the color the more acute the disease. Scales, ulcers and scars are found in chronic diseases Single ulcers are found in one of four conditions—syphilis, trophic disturbances, traumatism and malignant disease. When occurring on the face, ulcers are almost invariably due to cancer, syphilis or tuberculosis Sometimes the odor is of some diagnostic value The syphilitic ulcer smells rancid, favus has a mousy odor, varicose ulcers are said to smell sweet, neurotic ulcers and leprosy, nauseous and foul, while the rodent ulcer has the odor of putrid meat Many chronic diseases of the skin are but the local manifestations of a constitutional condition and are characterized by the formation of inflammatory granulation tubercles The most familiar types are syphilis, tuberculosis, leprosy, glanders and actinomycosis The author continues his article by a very full discussion of the syphilitic and tubercular skin eruptions

46 **Earache.**—The acute engorgement of the vessels of the mucous membrane of the middle ear and the vessels of the contiguous regions causes pain by stretching of and pressure against the local nerves of sensation This is technically called otalgia, and is known popularly as earache Stillman discusses this very common condition, and calls attention to the necessity of a more thorough examination into the causes of earache. Some of these causes are affections of the pinna, especially inflammatory in character, perichronditis erysipelas, or an abscess on the auricle, the pressure exerted by the riding bow of glasses a circumscribed or diffuse purulent inflammation in the external meatus a diffuse inflammation of the skin or periosteum of the meatus during the course of middle ear abscess, indicating a blocking up of the mastoid an

tium, a foreign body in the ear, neoplasm, neuralgia, acute otitis media and acute otitis media purulenta and its sequela, and the exacerbations and sequelæ of chronic otitis media purulenta In the earaches due to some of these causes the diagnosis can be made quite readily, but in others we are likely to be led astray, especially in the case of children and those adults who are unable to locate definitely the seat of pain The only way to find out positively what produces the otalgia is to look at the parts, making a routine examination All that is needed in most cases is a flat wicked lamp, a metal or hard rubber cone speculum and a short focal distance head mirror For operative work under an anesthetic, it will be found convenient to have a forehead electric lamp Whenever possible, the case should be sent to the specialist, who is prepared to do everything, but many of these cases can not or will not go to the specialist, and it devolves on the general practitioner to make an examination, and he should be prepared to do so

49 *Address State Medical Society of Wisconsin F L Walbridge
50 *Borderline Between Medicine and Surgery J C Wilson
51 *Traumatic Asphyxia F Shimonek
52 Arterial Sclerosis J S Walbridge

49 —See abstract in The Journal of July 2, p 65

50 —Ibid, p 66

51 **Traumatic Asphyxia** —Another case of this kind is published by Shimonek, only a few cases in which recovery took place are recorded in the literature The patient, a robust young man, a house-mover by occupation, was pressed to the ground by a large piece of timber falling on his back while he was in a prone position When first seen by the author the patient was unconscious, breathless, his eyes were intensely congested and protruded from the orbits, his lips were swollen, the mouth open, and from it protruded his greatly swollen and black tongue The pulse was slow and strong, the heart was beating against the chest wall with great vigor The median basilic vein was immediately opened in order to relieve the congested right heart this procedure being deemed more necessary than the induction of artificial respiration The blood flowed in a large, black stream, and by the time one quart had escaped respiration commenced In the course of about an hour the circulation became equalized, and the patient was fully conscious With the exception of a little cough and some mucous râles in his chest, his health was fully restored, and he resumed work in a few days Shimonek emphasizes the necessity of the immediate performance of venesection in traumatic asphyxia Artificial respiration and the inhalation of oxygen should be used as auxiliaries only and should not be relied on to affect the cure After the great pressure in the venous system is reduced by venesection, then—if it seems necessary—both of the methods might be utilized advantageously

July

53 *Ureteral Calculus Operation Cure J B Kennedy
54 *Pruritus Ani W L Dickinson
55 *Chronic Irritation in the Etiology of Carcinoma H S Olney
56 Venereal Statistics in Michigan Albert E Carrier

53 **Ureteral Calculus** —Kennedy comments on the uncertainty of making a diagnosis of ureteral calculus, and cites a case in point, in which the calculus was located in the left ureter, a short distance above the bladder The patient had had indefinite symptoms, which he called "side ache," for six years before he consented to an operation The first incision commenced at the anterior extremity of the last false rib, proceeding downward to the ileum, following the line of the crista ilii, and terminating at the superior anterior spinous process of that bone The abdominal muscles were divided to the extent of about an inch, close to the superior anterior spinous process, down to the peritoneum The ureter was lifted up and the stone removed through a longitudinal incision This incision was closed with a continuous fine catgut suture, and the incision in the abdominal wall was closed by three rows of sutures The patient had a complete and uneventful recovery The stone, of the mulberry variety, weighed exactly 58 grains

54 **Pruritus Ani** —This subject is discussed by Dickinson, who emphasizes the importance of searching for the cause of the irritation and not merely to limit the treatment to local applications The prophylactic treatment, too, is of importance and should be insisted on Opium and morphin are contraindicated, even when sleeplessness is very marked and causes the patient much discomfort, because on the day following their use the itching is greatly increased To produce sleep the bromids, chloral hydrate, sulphonal, trional and phenacetin give the best results Hot water compresses, cocain lotion or ice bags applied locally sometimes afford temporary relief To allay the intense itching a lotion composed of carbolic acid, 30 drops, and olive oil, 1 ounce, may be applied twice daily If there is much thickening of the integument and an entire loss of pigment, pure carbolic acid or tincture of iodin can be used This will produce considerable soreness for a few days, and when healing is taking place, any remaining spots of thickened integument should be painted Citrin ointment, well rubbed into the integument, sometimes gives better relief than tincture of iodin or carbolic acid

55 **Chronic Irritation and Carcinoma** —The effect of chronic irritation in the causation of carcinoma is discussed by Olney whose observations lead him to draw the following conclusions 1 It is not necessary to presuppose the existence of embryonic inclusions at the location of the tumor formation, but the carcinoma may develop from the tissues normally present 2 Chronic irritation, mechanical or chemical produces a cellular proliferation, sometimes giving rise to a papilloma or adenoma, and, when resistance of the opposing tissues is slight or the irritation long continued, to a typical carcinoma 3 Parasites, if present in carcinomatous tissues have no more etiologic significance than any other form of chronic irritation and hence there are no specific organisms of carcinoma

65 Case of Strangulated Hernia, Operation Recovery J D Southard

57 **Combined Extra- and Intra-Uterine Pregnancy** —Cooper reports a case of this kind on which he operated and found an enlarged uterus with a distended right tube The tube was dark and mottled, and seemed on the point of bursting The omentum was adherent Some old dark clots were found in the cul de sac The tube and ovary were tied off and removed The uterus was not handled The abdominal cavity was left full of hot salt solution, and the wound closed with catgut and silkworm gut suture The patient recovered from the operation, but twenty one days afterward she expelled a live four months fetus Septic infection supervened and she died of septic peritonitis

61 **Combined Typhoid and Malarial Fever** —A case is reported by McGehee showing that it is possible to have typhoid and malarial infection in the same patient at the same time More systematic blood examinations of cases with irregular temperature curves would, perhaps, reveal the fact that the combination of the two diseases is more common in the southern states than is believed A short time previous to the onset of the typhoid, in the case reported, probably during the prodromal period, there was a distinct malarial infection, as evidenced by the history, the clinical symptoms and the blood examination It is a question whether this was a fresh infection or one carried over from the previous year It yielded promptly to quinin the parasites disappeared from the blood, followed by typhoid of a typical type, at the end of which there was another

marked manifestation of the malarial infection, the reappearance of the parasites in the peripheral blood yielding promptly to quinin, followed by mild intercurrent relapse, characterized by remittent fever, return of abdominal symptoms, etc.

66. **Family Physician as a Life Insurance Examiner.**—Greene deprecates the conditions existing at present which prohibit the family physician from giving any information as to the physical condition of an applicant for insurance, inasmuch as it is not fair to the insurance company toward whom the physician occupies a position as its trusted and confidential agent. He is in duty bound to see that the company receives the information vital to its interests or to decline the risk outright. The physician should keep his relationship with his patients separate and distinct from his duties as an insurance examiner. In the one case he owes his patient medical service, in the other his primary obligation is to the company. The writer believes that many examiners never take the applicant's temperature and never make a detailed analysis of the urine. This is partly due to carelessness on the part of the examiner and the willful disregard to the company's instructions. On the other hand the insurance companies deserve censure. First because they have not made the physician understand that they demand thorough and careful examinations, and that they will support and protect good men in the performance of their duties. Second, because in many companies the medical report is reviewed and forwarded by the agent. Third, because a few companies do not absolutely protect the examiner in confidential communication.

68. **Insanity and Life Insurance.**—Dewey emphasizes the importance of early recognition of insanity in life insurance examination. He is convinced that many cases receive insurance while in the prodromal or incipent stage of insanity. This is due largely to the fact that little or no instruction is given in mental medicine in the medical schools, and, therefore, otherwise able and well informed practitioners and examiners for insurance companies are often "all at sea." The family history of the applicant should be gone into very carefully and thoroughly. Causes of death, such as "nervous prostration" or "nervous breakdown" from overwork or overstudy may generally be taken as a euphemism for insanity. Suicide as a cause of death should put the examiner on his guard, although it should not be taken as a positive evidence of insanity. The investigation should include inquiry into all serious illnesses and periods of incapacity for business and also as to treatment in any institution. Any marked mental change without adequate external cause should be regarded with suspicion. Neurasthenia, hysteria, hypochondria, may be early stages of insanity.

77 *Case of Acute Delirium in a Seven-year-old Child Probably Caused by Atropin Poisoning. I. A. Abt.

74. **Intussusception Cured by Sloughing.**—Snow reports a case of subacute intussusception occurring in a baby seven months old. The duration of the illness was sixteen days. The symptoms simulated an acute attack of ileocolitis. On the sixteenth day there was protrusion from the anus of a mass looking like ragged membrane, measuring one and one-half inches long and three-quarters of an inch wide, which could not be replaced by moderate pressure. A rectal examination showed that the mass traversed the rectum and emerged from the sigmoid flexure. The protruding tissue was a necrotic intestine, the result of intussusception. The case was operated on and six inches of the necrotic bowel protruding beyond the sphincter were removed by ligature. The baby recovered completely without any untoward result.

77. **Acute Delirium in a Seven-Year-Old Child.**—Abt reports a case of enuresis nocturna in a seven-year-old child which was followed by an acute delirium, due probably to atropin poisoning. The facts in favor of this supposition were the history of the continuous use of atropin, dilatation of the pupils, dizziness, blushing or flushing noticed for several days prior to the onset of the delirium and the delirium itself. The pulse continued normal in quality and rate, the respirations were not much increased, two unusual features in atropin poisoning. That the child continued apparently well until of a sudden the delirium developed is an unusual manifestation in atropin poisoning. For a period of three and one-half months the patient had been taking 1/200 gr. of atropin twice a day.

82 Common Deformities of the Spine. Henry Ling Taylor.

78. **Intra-Uterine Exploration for Diagnostic Purposes.**—The value of intrauterine exploration for diagnostic purposes is attested by Brothers. He considers the sound, the curette, the placental forceps and palpation as means to this end. The dangers connected with the passing of the sound into the uterus are, 1, interrupting a possible pregnancy, 2, exciting an intrauterine inflammation or pelvic peritonitis, 3, introducing sepsis into the uterine interior with resulting suppurative processes in the Fallopian tubes, and, 4, perforation of the uterine wall. The exceptional indications which justify the use of this instrument are, 1, patency of the internal and external os, 2, patency of the uterine interior, 3, relation of uterus to a tumor, 4, presence of an intrauterine polyp or a submucous fibroid, 5, determination of the size of an undeveloped or hyperinvoluted uterus. Constriction at the internal os is one of the most frequent causes of dysmenorrhea and sterility and can only be positively established by resort to the uterine sound. In a few instances sterility has been cured as a result of the examination. Pelvic tumors can not always be clearly differentiated from the uterus without the aid of a sound. The chief danger from the use of the curette is perforation. There may be a persistence of pelvic peritonitis, or agglutination of the raw surfaces of the uterus with a complete obliteration of the uterine cavity. The contraindications to curettage are pelvic inflammation and ectopic gestation. The curette gives the most precise information concerning the structure of the uterine interior. The scrapings, examined under the microscope, will reveal the condition present. The placental forceps possesses combined diagnostic and therapeutic qualities. Ordinarily, however, when this instrument is used the diagnosis has usually been fairly established by other means. The placental forceps must be used cautiously in the puerperal uterus, a few cases are on record in which the operator perforated the uterine wall and brought down omentum or a coil of intestine. Examination of the uterine interior with the finger is a very valuable method, although it is not resorted to as often as is desirable. The co-existence of perimetric or pelvic peritonitis is a serious contraindication to intrauterine palpation. The small uterus offers an insuperable obstacle to this method of examination. In all cases preliminary dilatation of the cervix is necessary. The method is of value in certain cases of malignancy of the body of the uterus, in deciduoma malignum, in

foreign bodies in utero, in polypi, in submucous fibroids and in incomplete inversions of the uterus

79 **Pancreatic Diseases**—Satterthwaite discusses the significance of various symptoms as far as pancreatic disease is concerned, and makes the following deductions 1 Pancreatic hemorrhage may be due to trauma, hemorrhagic diathesis, arteriosclerosis, cholelithiasis or intestinal contents injected through the common duct into the pancreatic duct 2 Acute pancreatitis, hemorrhagic or otherwise, is difficult of recognition prior to laparotomy chiefly because there is not sufficient time for the proper consideration of the circumstances of the case Mild cases may get well without a surgical operation The mortality is at least 80 per cent If the attack is due to gallstones extraction and drainage is likely to give relief 3 The mortality in chronic peritonitis from various causes may be as low as 4 per cent 4 The mortality in operations for pancreatic cyst has been 9 per cent Enucleation is only advisable when the cyst is pedunculated 5 As in cholelithiasis, expectant and palliative treatment in mild cases of the acute form will be likely to show favorable results The use of pancreatin offers promise It is given in ¾ gr doses three or four times a day The author reports thirteen cases, six carcinomatous and several due to secondary infection, in which there was absolutely no hope In two the implication of the pancreas was coincident with cirrhosis of the liver, in one with cirrhosis and peritonitis In only two cases, one of hemorrhage and one of cholelithiasis, could a surgical operation have afforded permanent relief

80 **Retrobulbar Neuritis, Strychnin Injections**—The treatment of atrophy of the optic nerve by hypodermic injections of strychnin was originated by Nagel Roosa says that the best results are achieved by making the injections in the temporal region and in the arm, and in some cases it may be necessary to give the strychnin internally Alcohol and nicotin amblyopia are the forms of disease of the optic nerve most frequently treated by hypodermic injection of strychnia If, however atrophy actually occurs it is certain that a cure is not to be expected An atrophic process may be arrested, but not cured The initial lesion in a toxic amblyopia is a neuritis in the orbital part of the optic nerve, retrobulbar neuritis, which leads to atrophy unchecked, but if recognized early enough, and appropriate preventive treatment be undertaken, a cure results When the case is of spinal or cerebral origin, or a syphilitic infection strychnin is useful The author reports nine cases, only two of which were cured The average dose of strychnin injected in these cases varied from 1/3 to 31/60 gr One case received 9/16 gr three times a day The maximum dose given to any case hypodermically was 4/5 gr and per orum ¾ gr three times a day

2 Sanitation in Volunteer Camps and the Disposal of Refuse and Excreta P B Giles
3 *Naval Dietary J Falconer Hall
4 *Duties of a Medical Officer with a Regimental Unit in the Field J F Donegan
5 *On Sterilization of Infective Discharges and Utensils on Field Service A M Davies.
6 The Recruiting Problem (To be continued) W C Beevor

1 **Camp Sanitation**—Freeman considers this important subject under temporary and stationary camps He discusses the selection of suitable sites and considers the ridge pole tent as compared with the bell tent, lays special stress on the water supply, which should be kept uncontaminated, in place of the filtered water in the field, he prefers boiled water issued in the form of weak tea, the careful policing of the field kitchens is advised, and especially that the kitchens and latrines should be kept as far from each other as possible. He lays especial stress on the latrines and advises the pail system rather than the use of trenches, as in the former the excreta are removed from the camp altogether instead of being buried He advocates the burning of all camp refuse so far as practicable

3 **Naval Dietary**—J Falconer Hall shows in graphic form a new dietary scale for the navy compared with the old scale The following articles have been added to the ration Preserved meat, ¼ pound, sugar, 1 ounce, tea, ⅛ ounce, fresh vegetables, ½ pound, with fresh meat, condensed milk, ¾ ounce, jam, 2 ounces, coffee, ½ ounce, raisins, ½ ounce, with salt and preserved meat, compressed vegetables 1 ounce, with salt pork or beef and preserved meat The following articles have been reduced by ¼ pound per diem fresh meat, salt pork and salt beef The ration of chocolate has been reduced by ⅜ ounce, and that of preserved meat by 3 ounces per diem.

4 **Duties of a Medical Officer with a Regimental Unit in the Field.**—Major Donegan takes up the difficult problem of the distribution of medical officers in the field. In his opinion the senior medical officer of the force should have the power to utilize his medical officers as he thinks best, and to send them where they are wanted, instead of the cast iron allotment per regiment The duties of the regimental medical officer in the field are 1 To be with his unit under fire in charge of regimental bearers, 2, to see the morning sick of his corps, and to send such sick, other than those suffering from minor ailments, to the brigade field hospital, 3, to attend to the sanitation of the camp, as far as it pertains to his own unit He proposes to modify the present system so that with an ample supply of medical officers a surplus medical officer is detailed to each unit on the understanding that his appointment is temporary and that he can be transferred whenever required He regards the equipment issued to the medical officer excessive and cumbersome, and suggests that the regimental medical case should contain modern tooth instruments, a surgeon's pocket case, some forceps, retractors, tourniquets, ligatures in bottles, chloroform in capsules, two waterproof sheets and two small dressing trays, antiseptic tablets, adhesive plaster, bandages, dressings and syringes For medical assistance he would add two thermometers, one stethoscope, one hypodermic syringe, with extra needles, a pocket case of medicine, a strong candle reading lamp, spare bandages, surgical dressings, etc He would divide the equipment of the unit into three classes, 1 The ordinary equipment, which consists of the hospital complete, 2, modified equipment in which all is left behind that is not urgently required, and 3, emergency equipment He attaches the greatest importance to first field dressings and suggests that instead of having the dressing carried in the pocket of the jacket, which is likely to be discarded in hot weather or in action, it should be made a part of the bandolier, properly sealed up Transport to a medical unit is all important as without transportation the unit is powerless to be of the slightest assistance. The author recommends, therefore, that all ambulance wagons and medical equipment wagons should be directly under the orders of the medical officer

5 **Sterilization of Infective Discharges and Utensils in Field Service**—Davies gives the following four methods of dealing with infective discharges as the only ones that are likely to be carried out in practice 1 Burial in earth, either in deep or shallow trenches, 2, treatment with disinfectants followed by burial, 3, sterilization by moist heat, followed by burial, 4, destruction by fire—that is, incineration

The Lancet, London.

August 6

7 *Cerebral Invasion of Pathogenic and Pyogenic Organisms and on the Choice of Ligatures William Macewen
8 Bright's Disease and Its Varieties John Rose Bradford
9 *Diaphragmatic Hernia of the Stomach and on Torsion of the Small Omentum and Volvulus of the Stomach in Association with It R. Lawford Knaggs
10 *Heart Lesions Some Points in Their Diagnosis and Treatment John Hill Abram
11 Relation of Inebriety to Insanity and Its Treatment. Robert Jones
12 *Contribution to the Sero therapeutic Treatment of Anthrax Two Cases of General Anthrax Infection in Man Cured with Anti anthrax Serum Ivo Bandi
13 Case of Removal of the Appendix on a Royal Mail Steamer at Sea Recovery T H Macfie
14 *Note on Home-made Humanised Milk C Beauchamp Hall
15 Extra uterine Gestation a Full term Child Removed by Operation Four Months After Fetal Death George D Wherry

7 **Cerebral Invasion of Pathogenic Germs.**—Macewen says that the anatomic features are often secondary determining factors between abscess and meningitis, and in the latter case between localized and generalized lesions If the access of the pyogenic organisms has been by way of the tegmen or the sigmoid, abscess of the brain or cerebellum is frequent, and if meningitis results it is, at least, primarily localized, does not immediately involve vital structures, and is often amenable to prompt treatment If the pyogenic organisms have traveled by way of the internal auditory meatus they occasion leptomeningitis of a serious kind on account of its being basal, early involving the medulla and respiratory centers, and, secondarily, on account of its inaccessibility Abscess of the brain seldom or never occurs by pyogenic organisms traveling by way of the internal auditory meatus Pus in the meshes of the pia mater and arachnoid occasionally produces softening and ulceration of the brain surface, but not abscess of the brain Patients affected with tubercle of the middle ear, with rupture of the membrana tympani are subject to secondary pyogenic invasion, which runs a rapid course. The author also discusses the choice of suitable material for ligatures and sutures and the requirements of the living tissue relative to them Catgut is one of the best of these materials, but care ought to be exercised in choosing good material. For ligatures and sutures raw catgut ought to be selected, preference being given to such

specimens as present the best physical properties and show that care has been bestowed on their manufacture Before use the catgut should be placed in a solution which increases the resistance of the gut to the action of living tissue As the resistance required varies according to the use to which the catgut is put, so the catgut is prepared with various degrees of resisting power, some hanks are prepared for rapid absorption, and some are prepared to resist absorption for long periods The gut must not be hardened in such a way as to prevent leucocytal penetration, otherwise it will be too resistant, and be no better than silk or wire One of the best media to be used for this purpose is one consisting of an aqueous solution of chromic acid and glycerin in definite proportions The longer the catgut is kept in this solution the more resistant it becomes After it has been prepared properly it is stored in a carbolized glycerin solution for two weeks, when it is ready for use The greater the vascularity of the part the quicker will be the absorption, while marked avascularity retards absorption Over contraction of the tissues or over tightening of the suture at the time of introduction also retard absorption, and so, too, the introduction of the gut into tissues deprived of their vascularity or the vitality of which is otherwise lowered In the midst of suppuration, an impervious suture is the best If catgut is introduced into a collection of fluid in the midst of living tissue, it will remain for weeks macerated but still intact It is evident that maceration does not account for absorption The use of proper material, such as is described in the article, is of service in facilitating wound healing It is no longer necessary to disturb the patient by dressing in order to remove sutures which, after they have served their function will be removed perfectly by the activity of the living cells in the patient's body

9 **Diaphragmatic Hernia of the Stomach**—Knaggs considers diaphragmatic hernia of the stomach and torsion of the small omentum and volvulus of the stomach in association with it, with reference to the causes, symptoms, pathology and treatment, and reports four cases

10 **Diagnosis and Treatment of Hernia**—Abram emphasizes the importance of thorough and careful examinations of the heart when symptoms, such as palpitation, murmurs of hemic origin and hemoptysis, exist Oftentimes they are an evidence of disease of the nervous system or of tumors pressing on nerves A cursory examination is insufficient Auscultation alone will not disclose the actual condition, a careful physical examination is necessary The author discusses the treatment with reference to (1) compensation practically equal to the lesion, (2) compensation only equal to the lesion when the patient is at rest, and (3) compensation unequal to the lesion, but offers nothing new

12 **Serum Treatment of Anthrax.**—Bandi reports two cases of general anthrax infection in man that were cured with antianthrax serum In both cases the clinical and bacteriologic examination confirmed the diagnosis The serum was used when the signs of serious general poisoning were chiefly apparent in the edema which had spread far from the primitive seat of infection, in grave disturbances of the circulation and in the evident lesions of the kidneys In the first, the most serious of the two cases, the action of the serum was rapidly decisive when free cauterization of the primary focus of infection had completely failed. The double action of the serum was evident, its anti bacterial power shown by the arrest of the infection, and its antitoxic power by the improvement in the general condition and by the complete restitution of the renal function immediately after the use of the serum The author insists on the necessity of treating such severe cases energetically by injecting into the veins large doses of the serum In the first case 150 c c were injected intravenously, no subcutaneous injection was made In the second case he injected 80 c c intravenously and 30 c c subcutaneously

14 **"Humanized" Milk**—Hall vaunts the excellency of his method of preparing cow's milk to be used by infants He calls the final product "humanized" milk In preparing he makes use of a tablet containing sufficient rennet to curdle half a pint of milk, one and a half grains of bicarbonate of sodium, one half grain of calcium phosphate, and five grains of lactose These tablets make a mixture almost identical with human milk The "humanized" milk is prepared as follows Boil or sterilize half a pint of cow's milk Skim another half a pint and add it to the first half pint Crush one tablet, and when the skimmed half pint has been heated to 100 F add the tablet stir, and keep it about the same temperature for twenty minutes Separate the curd thus produced and boil the whey for two minutes Add this whey to the first half pint of milk, and to this mixture add three ounces (6 tablespoonfuls) of boiled or sterilized cow's milk Soak all vessels used in boiling water before and after using The quantities given in these directions make one pint This method has proven extremely satisfactory in the author's experience

17 A Criticism of the Mosquito Theory of Infection in Malaria and Yellow Fever L Cheinisse
18 *The Criminal Responsibility of the Alcoholic Wm C Sullivan
19 The Vestiges of Syphilis Frank H Barendt

18 **Criminal Responsibility of the Alcoholic**—The question of responsibility, says Sullivan, arises in connection with three conditions (1) Chronic alcoholic insanity, (2) delirium tremens and (3) the dreamy mental state of morbid drunkenness The admission of morbid drunkenness as a condition excluding full responsibility is especially desirable in that it would further the trend of public opinion to adopt preventive measures against the criminal alcoholic When the chronic alcoholic has once shown the disposition to dream states with impulsive tendencies, especially homicidal or suicidal, he ought to be dealt with on the same footing as the impulsive epileptic—immune from ordinary punishment, but unfit for ordinary freedom

20 **Stovaine**—The new synthetic analgesic has shown itself in experimental tests similar in its action to cocain It abolishes the vital properties of the cells with which it comes in contact and acts as a poison to the central nervous system It is considerably less toxic than cocain, and this, in connection with its tonic action on the heart, its antithermic action and its antiseptic properties, promise a fine future for it from the therapeutic point of view Huchard related a number of clinical experiences with it during the last two months He found it most effectual when injected along the course of an aching nerve and in epidural injections Not the slightest symptom of intolerance was observed after injection of 1 to 3 cg, even when the patients neglected to lie down afterward (See page 575, in last issue)

22 **Bromin in Treatment of Diphtheria**—Bascoul practices in Algiers, where it is not always possible to obtain fresh anti diphtheria serum In the lack of it, he uses bromin, and states that seven years of experience with it have demonstrated its great efficacy He administers five to ten drops of bromin in 200 gm of sweetened water, with 3 gm of potassium iodid He uses for a gargle the same with 20 to 30 drops of the bromin He applies this treatment to all kinds of sore throats, including those of the eruptive fevers and has found it both certain and effectual

26 **Acute Catarrhal Arthritis.**—This communication from Küster's clinic describes 2 cases of pneumococcic arthritis which, the author states, bring the number on record to 55 The patients were 11 months and 16 years old and the cases confirm the assumed benignity of such pneumococcic processes in children They were treated by puncture, aspiration and injections of iodoform glycerin, but severer cases require more vigorous measures In the infant there was a mixed infection with the proteus, and in the other a pneumococcic knee trouble coinciding with an acute osteomyelitis of the femur on the same side, but caused by a diplococcus of another kind

28 **Differential Diagnosis of Gastric Motility and Hypersecretion.**—Strauss claims priority for Elsner's test (described in The Journal recently, page 360), and adds that his technic is simpler and more reliable His name for it is the Schichtungsprobe," which may be translated the "stratification test," as it is based on comparison of the spontaneous sediment with the total amount of stomach content His detailed article on the subject and his conclusions have just been published in the Riegel *Festschrift*, which forms vol liii of the *Zeitschrift f klin Med* He does not accept the findings of the stratification quotient with as much confidence as Elsner, as he found a quotient of 60 per cent and over in certain cases with free HCl, and not a trace of motor disturbances He has also found quotients of 4 to 8 per cent., both with and without motor incompetency

29 **Laryngeal Tuberculosis and Pregnancy**—Sokolowsky advocated interruption of the pregnancy in 2 women with advanced laryngeal tuberculosis The disease had made giant strides during the pregnancy, which was in the sixth and eight months when the patients were first seen Both succumbed within four weeks of the artificial delivery Goldkesen's 2 patients, under similar circumstances, died in three weeks Notwithstanding these unfortunate occurrences, the author reaffirms the importance and value of interrupting the pregnancy in every case of progressive laryngeal tuberculosis, but insists that it should be done during the first months of gestation He examines every woman with laryngeal tuberculosis for a possible pregnancy, and advocates artificial sterilization of such women

30 **Borax in Epilepsy**—Hoppe's observation of 12 epileptics treated with borax suggests that it may be found useful in the cases of epilepsy which are unfavorably affected by some existing stomach trouble Unmistakable benefit was apparent in 5 cases, although the borax has no specific influence on the disease

33 **Lecithin in the Kidney**—Dunham's analysis has shown that the lecithin in the kidney deserves far more attention than hitherto accorded An alcohol chloroform extract of kidney tissue contains much more lecithin than heretofore supposed, although the kidney can by no means be regarded as a deposit of fat

34 **Nail Healed in Heart.**—Koch found a nail, 3 cm long and from 1 75 to 3 mm thick, as a necropsy surprise in the heart of a robust man of 72, formerly a woodworker, who had died of senile bronchitis He reviews the literature on the subject, and states his grounds for the assumption that the nail had been suddenly driven into the heart from without, its direction, its position in the left ventricle and fixation in the septum, and the absence of any changes in the pericardium The family knew of no traumatism

37 **Diagnosis and Treatment of Tabes.**—Coester practices at Wiesbaden, and has frequently had occasion to diagnose tabes in persons sent to the spa on another diagnosis—rheumatism, neuralgia, etc He emphasizes the importance of an early diagnosis in order to institute mercurial treatment before the lesions have become irreparable From a material of 102 cases he warns that the first lightning, lancinating pains in tabes are almost invariably supposed to be rheumatic in their nature They generally appear first in the legs Paresthesias should also suggest the possibility of tabes, and also variations in sensibility Hypalgesia to analgesia is a particularly valuable sign of incipient tabes, especially when asymmetric His experience emphatically corroborates the view that tabes can be modified and even cured by mercurial treatment, or at least arrested in its progress The main thing is to institute it in the early stages Mercurial treatment never proved injurious in any of his cases He reports a number in detail One patient was a woman of 33, who complained that she had had severe headaches since the first of her ten years of married life, had aborted once, and had had transient abducent paralysis and double vision, the paralysis yielding to salicylates The headaches were chiefly occipital and in the region of the root of the nose, and there were occasional pains in the limbs, with hypesthesia and hypalgesia in the legs The diagnosis was at first hysteroneurasthenia with chlorosis, and the patient improved under arsenic and iron, electricity and baths She passed through a normal pregnancy, but afterward grew worse, and when seen again the diagnosis of typical tabes was unmistakable It probably had existed for many years, the headaches the first tangible symptom Years had been wasted on a diagnosis of gout and rheumatism The idea of mercurial treatment was suggested, but derided by a consultant, and slight transient improvement was realized under other measures The intolerable pains, gastric crises and frequent vomiting compelled the use of morphin Inunctions were finally commenced, resulting in the complete cessation of the pains and gastric crises The unmistakable benefit in this case proved an incentive to further application of specific treatment, but as all the cases observed were in the long established stage, the results were not what may be anticipated when commenced in the incipency of tabes This hope is justified by the recent announcements from France that lymphocytosis in the cerebro spinal fluid is a constant phenomenon in tabes and progressive paralysis

40 **Treatment of Unilateral Contraction of Thorax.**—The thorax is frequently found to be contracted on the side that has been the seat of some pleura or lung affection This is combated at Quincke's clinic by strapping in the sound side An apparatus is applied, shown in the illustration, which presses on the sound side, four strips of metal reaching from the shoulder nearly to the thigh on the affected side, the whole held in place by a ring around the thigh and straps around the shoulder

41 **Phototherapy After Sensibilization.**—Spiethoff reports from Lesser's clinic 6 cases of lupus treated on the lines sug

gested by Dreyer, noticed editorially on page 404 The results were entirely negative

44 **Surgery of Ureters**—Füth describes a case in which the functional test of the kidneys described in The Journal of Jan 2, 1904, page 69, proved of decided benefit and enabled the patient to be relieved of a fistula and restored to health The test was devised by Voelcker and Joseph and consists in the behavior of the kidneys after injection of 4 c c of a tepid solution of 4 gm carminum ceruleum in 10 c c of physiologic salt solution The injection was made in the buttocks It was supplemented by catheterization of the ureters, the findings showing that there was a small leak in the ureter causing the persistence of the fistula

45 **Avoidance of Ventrofixation**—Spaeth has found that in certain cases of backward displacement the adhesions, etc, are so extensive that if the uterus is allowed to sink back into its former place it soon grows as firmly in this malposition as before Ventrofixation prevents this, but is sometimes followed by dysmenorrheic disturbances To avoid this he has treated three patients by drawing the round ligament on each side through the internal inguinal ring and fastening the loop of the ligament in such a way that the uterus is held securely in its proper position A further advantage of this technic is as a prophylactic of hernia ,

49 **Responsibility of the Surgeon**—Kossmann urgently recommends surgeons to take out an insurance policy in some responsible society that insures physicians and surgeons against damage suits, etc He pays less than $3 a year and is guaranteed against financial loss from any suit resulting from his professional acts or those of any person for whom he is legally responsible He further asks the husband, parent or guardian of each patient entering the hospital in his charge to sign a certificate expressing their acquiescence in every measure which he, as the physician, thinks advisable He has never encountered any unwillingness to sign the certificate In conclusion, he urges the surgeon to act on the aggressive Without waiting for a criminal suit to be instituted, so soon as he learns that parties are contemplating such a step and are accusing him of malpractice, he should at once sue them for libel and place them on the defensive, instead of waiting to be attacked himself He will in most cases find that the other parties will apologize and retract their statements, after which he can withdraw his suit He adds that charlatans, and faddists generally, frequently pore over medical journals to find loopholes for attack, and advises medical writers to be cautious in making statements that can be misconstrued or exaggerated to the harm of the profession

50 **To Prevent Overlooking of Sponges, Etc, During Operations**—Kreutzmann has the compresses tied up in packages containing a dozen, and each dozen is plainly marked with indelible ink, 1, 2, 3 etc, or I, II, III, etc, or A, B, C, or a, b, c, etc Each package has thus its separate identity and the sponges from one can not be confounded with those from another package Before the operation he himself counts the compresses in each pile, to make sure that the dozen is complete After the operation all the compresses are thrown on the floor in rows corresponding to the original piles, and he glances over the rows to make sure that the dozens are all there He had a very narrow escape not long ago from leaving a compress in the abdomen, and since then has been taking these extra precautions which render such mistakes impossible

76 V Cnyrim Obituary

60 **Ultramicroscopic Findings in the Blood.**—The new ultramicroscope has revealed some hitherto unknown phenomena in the blood elements Raehlmann gives several illustrations of views of the blood cells, showing that they contain several little round bodies previously ignored Also that these bodies and the granules are in perpetual, active movement inside the cells, hopping around and to and fro for nearly half an hour after the blood has been drawn These findings were constant in man, animals and fishes in all the researches The serum and serous fluids also contain numerous particles of albumin in suspension, resembling yellow balls and gray dots, all hopping around in a lively manner, constantly changing their shape as well as place He thinks that these findings are important from the point of view of metabolism and the vital processes in general

61 **Myasthenic Paralysis.**—Oppenheim's patient was an otherwise healthy metal worker, 47 years old, who noted the sudden development of paralysis of both internal recti, with crossed double vision, fluctuating in intensity For an hour after waking in the morning he was free from symptoms The "myasthenic reaction" could be elicited from the left deltoid muscle Electric tests of apparently sound muscles are the best means of differentiating such a case from tabes Further evidence is the finding of the almost inevitable accompanying congenital anomaly of some kind, in this case it was polydactylia Foci of cellular infiltration have also been found in the muscles, with intact nervous system, in case of myasthenic paralysis Such foci are explained by Weigert as metastases of a malignant tumor, originating in the thymus The tumefied, degenerated remains of the thymus have some further share, probably, in the production of myasthenic paralysis This confirms the assumption that it is rooted in the soil of a congenital tendency, the German Anlage

64 **Operative Cure of Primary Diphtheria of Kidney**—Krause remarks that he has not heard of a case of kidney inflammation, treated by surgical intervention, in which the trouble was due to a pseudo membranous affection, as in the case he describes A young woman suffered from pains in the right side and back almost constantly during her first pregnancy Soon afterward she was struck in the right side and the pains recurred, with vomiting and bloody urine, for a week

or so A few weeks later symptoms of severe, acute right nephritis developed, with retention Krause opened up the right kidney and found a pseudomembranous process in the pelvis, with multiple, acute interstitial nephritis, but no suppuration, evidently on a predisposed soil The findings suggested primary diphtheria, although the Gram was negative The kidney was cleansed of the necrotic masses and held in the wound by loosely tamponing bandages after it had been opened like an open book, the raw surfaces covered with gauze Krause thus opens up all cases of kidney suppuration on which he operates, and his experience has been extremely satisfactory with this technic The kidney gradually subsides into place In the case described the cleft was only 3 cm deep by the seventeenth day and the wound had entirely healed a month later the patient gaining 15 pounds and dismissed in good health

65 **Azoospermia**—Posner and Cohn have encountered 35 cases of azoospermia in the last three years, and have treated 6 patients by making an anastomosis between the severed vas deferens and the head of the epididymis They state that they were inspired to this step by the success of similar operations on animals and man by Scaduto, Razumowski and Bogoljuboff in Europe, and by Martin, Carnett, Levi and Pennington in this country The interval between the undoubted cause of the obliteration—gonorrhea or mumps, or both—and the plastic operation was four to twenty seven years, the average nine The length of the interval is probably responsible for the lack of functional success in every instance The operation was well tolerated and the wound healed rapidly If undertaken earlier, while the *vis a tergo* is still adequate, functional success would be the rule They base their diagnosis on puncture of the testicle, when positive Negative results compel further exploratory measures The spermatozoa may not be motile the prostatic secretion may be necessary for this The stricture is usually multiple Physicians should strive to prevent obliteration of the passages by relics of gonorrheal or other inflammatory processes After the acute stage is passed systematic massage by Zabludowski's technic, iodin internally and similar preventive measures might be found useful Thiosinamin might possibly be used to advantage in these cases In any event, the physician should examine the semen occasionally after subsidence of an acute epididymitis, and as soon as azoospermia is discovered the patient should be instructed and prompt measures advised Semen can usually be obtained for examination by pressure on the prostate applied through the rectum, examining the urine also

68 **Eyelid Affections and the Scalp**—Albrand declares that it is absurd to neglect examination of the adjacent part of the scalp in case of lesions of the lids The scalp has almost as much to do with the pathology of the lids as the lachrymal ducts.

70 **Ulcus Rodens.**—Grawitz presents arguments to support his assumption of the epithelial nature of ulcus rodens The article is illustrated. He does not credit the existence of endotheliomata of the skin

71 **Successful Treatment of Pernicious Anemia.**—Grawitz is amazed that so little attention is paid to the treatment of pernicious anemia on the basis of an enterogenic origin The disease is only a secondary, severe degeneration of the blood cells with vigorous regenerative activity on the part of the marrow It is explainable by the assumption of some poison acting on the erythrocytes The poison may come from without (lead arsenic, morphin, carbonic acid, etc), but in the majority the poison is of auto-origin, absorbed from the intestines and acting as a specific toxin for the blood in predisposed subjects Cases of this latter kind can be cured by putting an end to the autointoxication, while the ideas that they are incurable, or to be treated only by albumin dieting and arsenic, are equally absurd He describes several cases out of his large experience of cures of pernicious anemia Case 1 was a multipara, 38 years old a milk man's wife, who presented the typical picture of pernicious anemia of sudden onset, with, beside the blood findings, edema, retinal hemorrhages and intense prostration enlarged spleen, slight icterus and ascites and slight temperature The teeth were badly decayed, the bowels torpid, the gastric motor function defective, and no free HCl could be discovered No medicines were given, but the mouth was put in good order and the diet restricted to vegetables and cereals, all mashed or in porridge form The stomach was rinsed out daily with tepid salt solution, and lemonade taken freely The animal albumin needed was given in the form of nutrient enemata after rinsing out the intestines with peppermint tea or salt solution A few drops of digitalis were given at first, but otherwise no medication Within a week the edema had subsided and the hemorrhages had been absorbed By the end of the second week the blood findings began to return to normal, and by the end of the month the patient had gained 18 pounds The nutrient enemata were discontinued during the third week, and the dietary enlarged, but the foods were all soft. A little hydrochloric acid was then given and Fowler's solution The patient was dismissed the picture of health, but returned before the year was out with a protracted suppurative pyelonephritis, to which she succumbed, but the blood findings never resembled those of pernicious anemia Case 2 was a workingman of 48, with acute delirium, râles at the apices, absence of free HCl, with the presence of albumin and indican in the urine, with the blood findings of pernicious anemia He was treated the same as Case 1, no drugs, except a few drops of hydrochloric acid Recovery was rapid, and the patient gained 23 pounds in four months The article is continued

72 **Reduction of Size of Nose**—Joseph gives illustrations of a few of the 43 patients for whom he has remodeled the nose He describes his technic of intranasal reduction of the protuberant bones, not incising the skin, and also his technic when the operation is done from without The scar is minimal, while the cosmetic results are perfect especially with the "scarless" method

73 **Value of the Marx-Ehrnrooth Biologic Test.**—Pfeiffer's experience with this test which was described on page 1393 of the last volume, was eminently corroborative of the author's statements Its chief value is for the control of the biologic blood test.

121 Report of Libel Suit Brought by 98 Physicians of Wiesbaden Against Dr A Pfeiffer See page 340

77 **Pathogenesis of Pneumonia** —Dürck believes that pathogenic germs are liable to be inhaled constantly into the lungs, but that they are promptly destroyed by the bactericidal forces at work there and absorbed Those found postmortem are the latest comers, and they are usually attenuated When the organism is depressed from any cause, especially by being chilled, the pneumococci present do not become attenuated, while the bactericidal defenses become weakened The result is liable to be a pneumococcic infection He placed rabbits in water just above the freezing point and kept them there for two to ten minutes, as in his experiments previously reported, but without preliminary heating About half the animals developed foci of pneumonic consolidation in a few days One rabbit died and both lungs were found consolidated to leathery consistency and entirely empty of air

78 **Oxygen in Photodynamic Fluorescence** —This latest announcement from Tappeiner that the presence of oxygen is indispensable to the photodynamic action of fluorescent substances, supplements the editorial on page 404 He has further found that active oxygen is constantly generated in photodynamic solutions exposed to the light

81 **Epilepsy of Pregnancy** —This communication from Erb's clinic describes a case of genuine epilepsy which developed during a pregnancy and subsided after its termination The observation emphasizes the fact that artificial interruption of the pregnancy is not necessary in such cases Systematic medicinal treatment will usually mitigate the symptoms, reducing the number and the severity of the convulsions His patient was a woman of 38, free from nervous tendencies or heredity, who had passed through 3 normal pregnancies and 3 abortions At the beginning of the eighth month of the seventh pregnancy partial epileptic seizures occurred, recurring every second day until delivery, then becoming less frequent and vanishing completely by the end of a month A pregnancy later was accompanied by the same convulsions, commencing at the eighth month, but much more intense and recurring sometimes twenty to thirty times a day The attacks lasted only three minutes and there was no loss of consciousness, and no sleep afterward Under bromid and chloral treatment the convulsions were somewhat improved, but the entire syndrome was permanently dispelled three weeks before delivery by an intercurrent, *febrile infection*, a bronchitis with an erysipeloid dermatitis of protracted course, accompanied by a psychosis, which lasted for two months after delivery The convulsions in this case indicated an affection of the lower parts of both right central convolutions, with slight participation of the other parts and adjoining convolutions The particulars of the case are given with much detail, and the connection between pregnancy and epilepsy corroborated with a review of the literature We note in the latter de la Motte's report of a woman who had epilepsy during 3 pregnancies, terminating in the birth of boys, while no symptoms of the kind were observed in the 5 pregnancies with girls A similar case has been reported by Van Swieten

84 **Self-Registering Thermometer** —Franz' "thermograph" consists of a thermometer set in a silver capsule which is fastened in the axilla A sensitive spring in the capsule transmits to a recording drum any variations in the temperature after the maximum has been determined The description is illustrated

85 **A Minute Sterilizer** —The aim is to use as little water as possible, apply the heat to as large a surface as possible, and utilize every particle of the water Kuhn accomplishes this by means of a long, wedge shaped trough, with a row of gas jets its entire length below

88 ***The Soil, Not the Water, the Transmitter of Cholera and Typhoid.***—Emmerich and Gemünd have been conducting extensive research which has demonstrated that the nitrates have remarkable power to enhance the virulence of cholera germs Guinea pigs tolerated without apparent reaction as much as 1 5 gm sodium nitrate ingested in 10 c c albumin They also tolerated a considerable amount of cholera bacilli per os But when the two were combined the animals rapidly succumbed with symptoms of cholera The same result must inevitably follow when man ingests cholera bacilli and nitrates The bacilli transform the nitrates into nitrites, and the latter cause the intoxication Plenty of nitrates are ingested in vegetables, etc , to cause severe intoxication when transformed into nitrites by any agency In a dry season plants contain an unusual amount of nitrates When there are no nitrates in the stomach the action of the cholera bacilli is comparatively mild Pettenkofer surmised that the soil, rather than the water, was the paramount factor in epidemics of cholera and this surmise has been confirmed by the research described It establishes that the drinking water can never be incriminated Water is rapidly cleared of pathogenic germs by the action of protozoa, especially the flagellates These are the guardian hosts of the drinking water, rapidly destroying all the pathogenic bacteria that find their way into it They accomplish this task in a few minutes in a brook or river, but may require several days for it in pure spring water Nature has protected water against pathogenic bacteria by the hosts of protozoa, the more polluted the water the more numerous the protozoa Typhoid and cholera bacilli multiply in the soil, not in the water, and only in the upper layers of the soil, where they can be easily reached and destroyed in combating epidemics Flushing the ground with water would accomplish this Fifty years ago Pettenkofer proclaimed that cholera germs might be imported and deposited in the stools, but that they alone were unable to induce an epidemic unless they encountered certain indispensable conditions, whose nature was still a mystery Emmerich and Gemünd believe that the results of their research supply the key to this mystery, namely, that "the ripening or exaltation of the virulence of the cholera bacilli" is dependent on an increased nitrite forming property in a soil peculiarly rich in nitrates They are convinced that prophylaxis should be along these lines, and that it is feasible and easy of realization

91 **Blood Platelets and Coagulation** —Bürker proclaims that *the amount of* fibrin depositing is in direct proportion to the number of blood platelets destroyed in the blood The destruction of the platelets also corresponds in time to the time of coagulation under the influence of varying temperatures When there is no coagulation, no blood platelets will be found to have been destroyed Coagulation in *freshly* drawn blood is connected with the typical destruction of the blood plates

93 **Agonal Leucocytosis.**—Arneth states that every disease has its special leucocytosis, and the agonal stage is merely the last phase of the specific leucocyte curve It varies with each disease

94 **Ammoniuria and Phosphaturia in Mental Disease**—Heinicke in his psychiatric practice was impressed with the frequency of phosphaturia and carbonaturia in his patients He has found manifest or latent ammoniuria or phosphaturia in every patient exhibiting a psychosis He further noted that the urine returned to normal as the mental affection progressed toward recovery The phosphaturia generally accompanied the height of the affection It is possible that the subsidence of the ammoniuria or phosphaturia may be an aid in prognosis, and their absence may also serve to reveal simulation

99 **Morphin in Heart Disease.**—Grassmann does not admit that heart affections should contraindicate the use of morphin in the usual therapeutic doses The sudden deaths that have followed the use of morphin in rare instances are on a plane with those observed from the use of chloroform, and are not to be explained by the assumption that morphin is a poison for the heart It should be given cautiously in acute processes in the endocardium or myocardium, as also in acute respiratory affections in persons with weak hearts It can be given freely in all purely functional nervous heart disturbances, especially in angina pectoris not due to organic causes, and even in the organic angina pectoris, stenocardia, small doses of morphin are allowable or even indicated It is unconditionally indicated in all severe cases of cardiac asthma, but its use is advisable only under great restrictions in the chronic dyspnea of ambulant cardiac subjects Morphin may prove very useful when digitalis and other heart remedies fail or have lost their efficacy It is also extremely valuable in excited, sleepless and debilitated patients as a preliminary to a course of digitalis

101 **Abortive Treatment of Gonorrhea**—Bettmann adds 10 gm of protargol to 45 gm cold water in a shallow dish and allows it to dissolve without stirring or shaking Glycerin is then added to bring the amount to 100 gm He prefers penciling to injecting the fluid, applying it daily to the anterior urethra for a distance of 6 to 8 cm in cases of acute gonorrhea Six to eight applications were sufficient in his experience with 42 patients, and no gonococci could be found thereafter in about half the number The treatment is less disagreeable than with silver nitrate Even in the incompletely aborted cases the course of the affection was remarkably mild. He considers this technic superior to others in vogue for several reasons, which he enumerates, especially for gonorrhea in the female, in recurrences, and in cases requiring rapid suppression of the secretion

102 **Diagnosis of Stenosis of Pylorus.**—Decker calls attention to the fact that an almost infallible sign of pyloric stenosis is afforded by the finding of the stomach content or parts of it in a well worked up homogeneous chyme. When the motor function is defective the food remains in coarse particles, but when it is strong enough to work the food into a soft, porridge like mass, it would certainly be able to expel the chyme from the stomach unless there were some obstruction at the pylorus In seeking for a tumor it is generally indispensable to determine the outlines of the stomach, as the pylorus is frequently concealed by the liver In 2 cases he differentiated the pyloric stenosis by the daily copious vomiting and hypersecretion

106 **Improved Technic of Treating Cervical Catarrh.**—Saniter is convinced that cervical catarrh is generally restricted to this part, and cites in warning Plien's recent statement that 7 out of 9 acute cases in his experience acquired annexitis from local treatment of the cervix Saniter attributes the infection in such cases to the cotton swab He avoids this by using asbestos fiber for the swab The fibers can be wound smooth around the sound or probe, and they take up the fluid as readily as cotton The asbestos wound probe can be held in a flame and burnt absolutely sterile He has his Playfair sounds made with a groove along the convex side, which allows the swab to be easily pulled off without contact with the fingers He uses microscope pincers for the purpose, as they hold the swab instead of allowing it to drop on the floor The groove in the sound also allows more fluid to be taken up than without it Swabs made on this principle will be found useful in rhinology, laryngology, etc, for cocainizing the urethra, cauterizing fistulas, etc

100 **Bence Jones' Albuminuria**—In the case reported the Bence Jones albuminoids were found constantly in the urine, the proportion ranging from 13 to 33 per cent No tube casts were ever found The patient was a man of 57, subject to gout, but otherwise apparently healthy The blood findings showed a leucocytosis of 10,000 to 11,000, predominantly lymphocytes, up to 60 per cent There were no indications of a bone affection, but something of the kind probably existed

112 **Local Anesthesia with Eucain.**—The number of operations at Czerny's clinic and dispensary increased respectively from 1,717 and 1,035 in 1897 to 1,955 and 1,502 in 1902 The increase in the number done by local anesthesia alone was from 91 and 21 in 1897 to 185 and 193 in 1902 During the latter year he witnessed the death of a patient from cocain local anesthesia Only 7 c c of a 1 per cent solution of cocain had been injected into the urethra, but convulsions and arrest of the heart and respiration followed immediately The patient was a young man with sexual neurasthenia and chronic prostatitis The fluid had remained in the urethra only two minutes at the utmost Since then eucain has been exclusively used for local anesthesia, with or without adrenalin, and it has been found perfectly satisfactory It is comparatively nontoxic, while an isosmotic, warmed solution of eucain induces anesthesia as effectively as cocain in the same strength Adrenalin enhances its action, and is free from by effects in subcutaneous injection, in concentrations of 1 to 20,000 The Oberst technic is preferred The list of operations done under eucain is given, 188 in all The supplementary adrenalin was particularly valuable in extirpation of deep tumors, lipomata, adenomata of mamma and struma, excision of small tumors of tongue and lips, angiomata, in operating on the jaws, and in small plastic operations Eucain is particularly useful as a preliminary to cystoscopy

117 **Individual Protection Against Mosquitoes and Yellow Fever**—Bassewitz affirms that the stegomyia absolutely refuses to bite when insect powder has been rubbed into the skin The powder to which he refers is the pulverized flowers of the *Chrysanthemum cinerarifolia* or *rosæ* When this powder is unadulterated and fresh, the hungriest stegomyia flees from it or dies after contact with it

128 *Azione del saccaromyces cerevisiæ sul bacterium coli nelle gastroenteritite infantili Puoti

123 **Intoxicant Action of Formalin**—Riggio's conclusions from his various groups of experimental researches are to the effect that formalin is a poison which induces intense hyperemia in the organs by which it is probably eliminated. This occurs both when the poison is administered subcutaneously or by inhalation The hyperemia is so intense that it induces hemorrhages in the liver, kidneys and lungs The formalin has also a destructive action on the cells of these organs, as he shows in detail

126 **Diplococcus Polyarthritis**—Baduel's patient had first an acute pneumonia This was followed by a slow suppurative process in the pleura in the course of which developed what was apparently an articular rheumatism, but was found to be a diplococcus affection The syndrome had many points in common with what Marie has described as "pneumic osteo arthropathy deformans" The joints were enlarged and the nail-

curved Marked improvement was observed after a course of treatment with a solution of Castrocaro salts

128 **Yeast in Infantile Gastroenteritis**—Puoti has observed great benefit from the administration of brewers' yeast in infantile gastrointestinal affections The symptoms are much improved, but the colon bacillus *in vitro* is not modified by the yeast He explains its favorable action as possibly due to a modification of the toxic products of the bacteria or to its influence on the organism itself, re enforcing its resisting powers

136 *Influence of Diphtheria Toxins on Heart and Respiration of Animals Krasnoff—Vliyanie diph toksina na serdtze i dykhanie zhevotnykh

129 **Gonorrheal Vulvo-Vaginitis in Little Girls.**—Rudsky has had occasion to treat 14 cases, and comments on the tedious course of this affection He found that the children tolerated protargol or largin well, and he used them in a 5 to 1 per cent solution In every instance the urethra was involved and required the silver treatment Eczema of the parts and anemia were the most annoying complications He introduced the solutions into the vagina with a soft catheter His review of articles on the subject includes a list of 64, all of European origin

130 **Diagnosis of Organic Tricuspid Insufficiency Complicating Other Cardiac Affections**—The first of the three cases reported with great detail was a case of mitral stenosis plus tricuspid insufficiency, with induration in one lung, chronic tumefaction of the spleen, cardiac cirrhosis of liver and universal edema The second was one of mitral and tricuspid insufficiency, pericarditis with adhesions and arteriosclerosis The third, a case of a mitral affection with insufficiency of the tricuspid and arteriosclerosis Schwartz summarizes further 3 other cases of organic tricuspid insufficiency observed during a recent trip to Germany His conclusions from study of this material are that organic tricuspid insufficiency complicating a lesion of the orifice of the left heart, is of more frequent occurrence than is generally recognized The principal sign is the comparatively insignificant enlargement of the area of cardiac dullness toward the right, accompanying other symptoms (positive vein and liver pulse) which in case of relative insufficiency of the tricuspid valve, are usually accompanied by extreme degrees of dilatation of the right ventricle The majority of authors mistakenly expatiate on the unfailing excessive dilatation of the right ventricle as the inevitable condition which differentiates organic tricuspid insufficiency Among the auxiliary signs, secondary in importance, may be mentioned the tendency to recurring ascites and induration of the walls of the jugularis, manifested by the behavior of the pulse wave The further course of the cases confirms the correctness of the diagnosis on this basis Our knowledge in regard to the course and the influence of organic tricuspid insufficiency on the course of other cardiac defects is contradictory, confused, inadequate and even without any positive basis Further study of these questions is urgently needed, and for this it is indispensable that clinical histories should be collected and published, recording the incipient phases As a contribution to the subject he presents these 3 cases with the postmortem findings in one They contradict in certain points the statements in the text books, with the exception of Merklen's work

133 **Cupric Citrate for Trachoma**—Sukhoff's conclusions from observation of 17 patients with trachoma, treated with cuprum citricum, are to the effect that this drug is excellent for the purpose The applications are comparatively painless, and the absence of all irritating properties allows the treatment to be repeated two or three times a day, which ensures the rapid subjugation of the pathologic process He used a 5 or 10 per cent strength

135 **Cryoscopy of Urine in Case of Pleuritic Effusions**—Usoff has been testing Koranyi's assertion that a convenient means of obtaining information in regard to effusions is afforded by cryoscopy of the urine The quotient of the freezing point divided by the percentage of sodium chlorid enables the course of the effusion to be determined This quotient parallels the variations in the amount of the pleural effusion, that is, it becomes larger in case of accumulations of fluid in the body, and grows smaller as the fluids are eliminated Usoff gives the findings in 5 cases They demonstrate that the quotient is liable to vary from other causes as well, fever, fluctuations in the amount of urine, etc, and that cryoscopy, therefore, can scarcely be depended on for reliable information

136 **Influence of Diphtheria Toxin on Heart and Respiration**—Krasnoff noted paralysis of the vasomotor centers in the medulla oblongata, and of Goltz' center in the course of experimental diphtheria in guinea pigs The peripheral vaso constrictor apparatus remained unaffected The paralysis of the vasomotor centers caused progressive decline in the blood pressure at the height of the intoxication The heart, secondarily irritated in consequence of the changed conditions in the blood vessels and the asphyxia, feels the effect of the toxin independently in the final stage of the intoxication, the cardiac rhythm becoming irregular, although the excitability and functional activity of the heart are retained Acute changes in the inhibiting apparatus were also observed, passing through two phases, first extreme excitability and then, paralysis of the vagus In connection with the paralysis of the vasomotors an acute drop in the temperature was observed Death occurred from paralysis of the respiratory apparatus

FURTHER STUDIES OF THE INTRACELLULAR BACTERIAL TOXINS *

VICTOR C VAUGHAN, M.D
ANN ARBOR, MICH

For the past eight years much of my time, so far as it could be given to research work, has been devoted to a study of the intracellular toxins of bacteria, and the purpose of this paper is to briefly state what I have accomplished along this line, and to formulate the theoretical conceptions that have grown out of this investigation In this work I have been aided by several most competent assistants and students, all of whom have labored without any remuneration worthy of mention, except that which comes to everyone who engages in scientific research intelligently and conscientiously In 1896 Perkins and I[1] reported the presence in a toxicogenic bacterium found in poisonous ice cream of an active body that proved to be soluble in alcohol, and in this respect, at least, as we shall see later, similar to the toxins which we have recently been studying

In 1900, with McClymonds,[2] I was able to demonstrate that the colon germ, so frequently found in cheese, produces no soluble poison, but that the cell substance is markedly toxic The bacterial cells were steamed and subsequently exposed for several days at 37 degrees to artificial gastric juice without destruction of their toxic properties In 1901, with the aid of Cooley and Gelston,[3] I was able to make substantial advances The large tanks, so necessary in order to obtain bacterial cell substance in large amount, were devised and put into operation Without these the work since accomplished could not have been done, because the production of large amounts of bacterial cell substance free from constituents of the culture medium and free from contamination was essential before the chemistry of the cell could be successfully investigated In a paper before the Association of American Physicians in 1901 I was able to make the following statements concerning the toxin of the colon bacillus

1 The toxin is contained within the cell from which it does not, at least under ordinary conditions, diffuse into the culture medium

2 The toxin is not extracted from the cell by alcohol or ether

3 Very dilute alkalies do not extract the toxin from the unbroken cells

4 The unbroken germs may be heated to a high temperature with water without destruction of their toxin

5 Boiling with a 0 2 per cent aqueous solution of hydrochloric acid has but little, if any, effect on the germ cell or its contained toxin

6 Heating the germ substance for an hour at the temperature of the water-bath with water containing from 1 to 5 per cent hydrochloric acid breaks up the cell and lessens, but does not destroy, the toxicity of the cell content Prolonged heating may render the toxin inert

In the paper referred to I spoke several times of the bacterial cell wall, a structure which I am now satisfied has no existence

In 1902 my students were able to make the following advances

(*a*) Detweiler[4] showed that the cellular substance of micrococcus prodigiosus, bacillus violaceous, and sarcina aurantiaca and sarcina lutea contains poisonous bodies

(*b*) Wheeler[5] demonstrated the presence in the cell substance of sarcina lutea of two carbohydrates, a nuclein body yielding xanthin basis (since obtained in crystalline form), and a proteid yielding hexon bases (also since obtained in crystals), thus showing that the cell is made up largely of a glyco-nucleo-proteid molecule

(*c*) Leach[6] split up the colon bacillus, and proved that it also contains in its molecular structure carbohydrates, nuclein and proteid

(*d*) Marshall and Gelston[7] determined with great accuracy the toxicity of the colon germ substance, and showed that with this immunity could be obtained, although it was neither marked nor permanent The germ substance is moreover, not a favorable agent to employ in inducing immunity on account of its insolubility

(*e*) Gelston[8] found an intracellular toxin in the bacillus of diphtheria, and showed that commercial antitoxin gives no protection against the intracellular poison

(*f*) J Walter Vaughan[9] demonstrated, contrary to the findings of all other investigators along this line that the anthrax bacillus does produce a poison, and that it is intracellular

In 1903, Wheeler[10] made some investigations which in my opinion, have thrown much light on the problem, inasmuch as they lead to the suggestion that the bacterial cell is essentially a chemical compound of definite and constant composition It was found that when the cellular substance is extracted with dilute acids, the portion split off is practically the same whether 0 1 or 1 per cent acid be employed Furthermore, it was demonstrated that the amido-nitrogen split off with acid is the same, whether 1 per cent, 5 per cent, or 33 1/3 per cent sulphuric acid be used

Leach[11] obtained additional information along the same line by the action of mineral acids on the colon bacillus

McIntyre[12] applied my methods to bacillus pyocyaneus, and demonstrated the existence of an intracellular poison in this organism

Munson and Spencer[13] showed that the hepatic cells of vertebrates may be split up with the production of a poisonous group

During the present year, Wheeler and I have been able, by acting on the germ substance with sodium alcoholate, to split off and obtain in soluble form highly poisonous groups This has been accomplished with the colon, typhoid and anthrax bacilli, and with all of these we have produced antibodies which neutralize the toxin, but so far we can not speak with certainty concerning their antibacterial action The colon toxin immunizes guinea-pigs against both itself and the living germ, but with the other organisms experiments have not been carried far enough to justify a statement one way or the other The colon toxin split off from the germ substance is still a complex body, and gives the biuret and Millon reaction It is freely soluble in water and absolute alcohol and insoluble in ether, petroleum ether and chloroform The alcoholic solution as obtained from the germ substance by the action of sodium alcoholate contains two bodies, or rather two groups of bodies, one of which is poisonous, while the other is not actively so, at least The toxin is precipitated from alcoholic solution by platinum chlorid, while the non-toxic body is left in solution Of the mixture of the two obtained by evaporation of the alcohol in vacuo 8 mg is the minimum lethal dose for guinea-pigs weighing from 300 to 400 grams, but only 15 per cent of this mixture is toxic This makes the minimum lethal dose of the toxin between 1 and 2 mg, or one part to from 300,000 to 400,000 parts of body weight of guinea-pig By administering gradually increased doses of this toxin, guinea-pigs are immunized, and when such immunized pigs receive 2 c c of a twenty-four-hour culture of a virulent colon bacillus, they are but slightly affected, while controls invariably die within from ten to twenty-four hours

That this is the specific toxin of the colon bacillus it seems to me there can be no doubt, because it gives immunity in the guinea-pig at least, to both dead and living cultures of the germ This toxin is, I believe composed of a haptophore and a toxophore group Concerning the nature of the former, I am not prepared as yet to express an opinion There are certain reasons for suspecting that the toxophore group is a neurin These reasons are both chemical and physiological Neurin is a highly poisonous body that is not decomposed on being boiled with sodium alcoholate, so is the colon toxin Neurin acts on the respiratory center and arrests the respiratory movements, while the heart continues to beat normally This is especially marked with our toxins, those obtained from the colon, typhoid and anthrax bacilli, most marked with the last mentioned When this poison is injected intravenously in doses of a fraction of a milligram, the respiratory movements cease immediately, while the heart continues to beat for five minutes or even longer It will be understood that these are only suggestions that the toxophore group is a neurin body They are by no means proofs and I hold the right to change my opinion on this point after further investigation As Behring has suggested the toxophore group may be the same in a number of different pathogenic bacteria.

When the dried colon germ substance is heated with sodium alcoholate, about one-third of the cellular substance goes into solution in the alcohol, while the rest of it remains out of solution All the toxin is dissolved in the alcohol, provided the extraction be repeated three or four times, but, as has been stated, of the one-third of the germ substance that goes into solution in the alcohol, only about 15 per cent is toxin

The part of the cell substance insoluble in alcohol is soluble in water, wholly on addition of traces of acid, and while non-poisonous, it is scarcely less interesting than the toxic part The aqueous solution contains a hemolysin and a group that splits up the hemoglobin into hematin and a globulin The hemolysin is precipitated from the aqueous solution by the addition of acid and the application of heat It is thermo-stable and can be heated to 110 degrees without appreciable loss of its hemolytic properties This promises to give us a rare opportunity of finding out something more definite than is known up to the present time concerning the nature of hemolysins I may say that traces of hemolysin have been previously found in colon cultures, and have been studied by Kayser,[14] who also found it to be thermo-stable This hemolysin is not active at low temperatures, and requires an incubation period before it manifests its effects So far as I know, this is the first time that it has been demonstrated that a hemolysin can be obtained by splitting up the bacterial cell with chemical agents It will probably be found that bacterial hemolysins are chemical groups in the bacterial molecule, and that those found in solution in culture media result from the normal disintegration of the bacterial molecule, which is always taking place with more or less rapidity I know of no previous observation of the group that splits up the hemoglobin molecule with the formation of hematin This body is now being investigated by Cooley in my laboratory, and a report of the work will be made later

Uniformly the bacterial toxins, so far as we have studied them, lower the temperature of guinea-pigs This is true of both fatal and non-fatal doses If the cellular substance of the colon bacillus be thrown into the abdominal cavity of a guinea-pig, the temperature begins to fall within two hours, and continues to do so as long as the animal lives, provided the dose is a fatal one If at any time the temperature ceases to fall and begins to rise, even after it has fallen below 95 F, the recovery of the animal can be safely predicted When the split-off toxin is injected the fall begins in a few minutes and continues to do so if the animal dies In case of recovery, the moment of change for the better is indicated by the beginning of a rise of temperature This matter also, as well as the destruction of the bacillus in the peritoneal cavity of immunized animals, is being studied in detail by V C Vaughan, Jr, and we hope to give more accurate information concerning the relation of the infectious diseases to temperature

[14] Ueber Bakterienhämolysine in Besonderen das Colilysin Zeitschrift f Hygiene 1903 xl 118

When the sterile germ substance of the colon bacillus is thrown into the abdominal cavity of a guinea-pig, a hemorrhagic peritonitis results When the split-off toxin is used in the same way death results, provided the dose be large enough, in a few minutes, and there is no evidence of irritation of the peritoneum When the dose is not fatal, recovery from the split-off toxin is apparently complete within two or three hours When the soluble toxin is injected intravenously death occurs within from five to twenty minutes, or with very minute doses there is no apparent effect

CONCLUSIONS

The investigations which I have hastily outlined have led me to the following conclusions

1 The colon bacillus in its essential part is a chemical compound as truly as sodium sulphate or phenylhydrazin.

I have been convinced of this by the following facts ascertained in our investigations

(*a*) When treated with dilute mineral acids, the body split off from the germ substance is uniform, both qualitatively and quantitatively, whether the acid employed be 0 1 per cent. or 1 per cent

(*b*) The amount of amido-nitrogen split off is the same, whether 1 per cent, 5 per cent, or 33 1/3 per cent. sulphuric acid be used. These findings indicate that the germ substance has a definite chemical composition, and that cleavage occurs along a definite line under the influence of the acid That the toxic, hemolytic, hemoglobin splitting, carbohydrate, and other groups are chemically combined in the cell, is indicated by the fact that they are not extracted by agents acting physically as solvents, but are separated only by those agents that split up molecules

2 The colon bacillus is a chemical compound, in whose molecule we have demonstrated the existence of the following groups Nuclein, amido, diamido, mono amido, carbohydrate, toxic, hemolytic, and hemoglobin splitting Graphically, we may represent the colon molecule as in Figure 1

There may be, and probably are, many other groups, then, each of these may, and probably does, contain subgroups Besides, these groups are attached to one another to form a highly complex molecule, and the lines along which the molecule splits up depend on the kind and the amount of the energy applied The force with which these groups are held in the molecular whole varies in strength,-consequently some groups are easily split off, while others are separated only under the influence of relatively powerful agents The toxic group in the molecule of some pathogenic bacteria drops off in the presence of moisture and at a temperature of 37 C This is true of those germs, such as the bacilli of tetanus and diphtheria, that are said to form soluble toxins. Many germs also have hemolytic groups which become detached from the molecule under similar conditions Some of the groups in the bacterial molecule are essential to the vitality of the cell Such I suppose to be the case with the nuclein group, while others are not essential The latter is probably true of the toxic group in certain bacteria, and this explains the fact that most pathogenic bacteria can be attenuated by growth in certain media, or under certain unusual conditions of temperature

3 Every cell in the animal body contains complex molecules similar to those of the bacillus As has been stated, my students, Munson and Spencer, have shown that a poison can be split off from the liver cell by the action of dilute mineral acids, and next year I hope to study the action of sodium alcoholate on these and other cells of the animal body

4 The reaction of the colon molecule and a body molecule or cell is chemical, just as much so as that between sulphuric acid and calcium carbonate When these two molecules are brought within the range of chemical attraction, if the chemism between a group in the one and a group in the other is greater than that which holds these groups in their respective molecules, a reaction takes place Each group is split off from its molecular combination, and the two combine to form a new molecule, and the injury done the bacillus or the cell depends on the group that has been abstracted No bacillus molecule can do the body cell harm unless such a reaction takes place It also follows that a toxin split off from a bacterial molecule and injected in the free state into an animal does harm, or breaks down the body molecules more promptly than when the unbroken bacillus is introduced, as sodium chlorid is not a poison, but if it be broken up into its constituent base and acid either of these, when introduced into the body, destroys the first cells with which it comes in contact This is, I think, nicely illustrated with our colon toxin The living culture or the dead germ substance, when placed in the abdominal cavity of a guinea-pig, requires from ten to twenty-four hours to kill, because the colon molecule must be split up before the toxic group becomes active, but when the free toxic group is employed, it may kill within as many minutes, because it is ready to combine with groups in the cell instantly on coming within range of their chemism Moreover, when the free toxin or toxic group is thrown into the abdominal cavity, it requires a longer time to kill than when injected intravenously because, in either case, it reacts with the cells with which it first comes in contact, and with which it is capable of combining When injected intravenously, some part of the free toxic group comes in contact with the cells of the respiratory center, and death, or at least arrest of the respiratory movements is almost instantaneous

h = Carbohydrate group

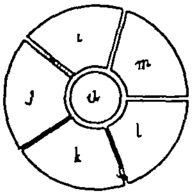

Fig 2 —Body cell

5 If this conception of the reaction between bacillus and cell be true, the formation of antitoxins is capable of an explanation, which seems to me simpler than any yet proposed This may be illustrated by the accompanying figures

Suppose that the chemical attraction between group "e" in the bacillus molecule, and group "m" in the cell molecule, is greater than that which holds these groups in their respective molecules then these groups will be broken away from their molecules and unite to form a new molecule, which, being saturated and stable, is not harmful The injury done to the cell will depend on the importance that group "m" bears to the functioning power of the cell, and the injury done to the animal depends on the number of cells whose physiologic function is thus interrupted I take it that a true toxin—understanding this term to apply only to those agents which are capable of producing antibodies in the animal organism—does not completely destroy cells It injures animal cells, but leaves them in such a condition that they can repair themselves Indeed, it seems to me that no other explanation is, at present, at least possible, because the formation of the anti-body is dependent on this process of repair, and an agent that destroys the body cells of the animal is a poison, but not a toxin It is not only possible, but probable, at the present time, that at least one pathogenic organism the tubercle bacillus, produces a poison which is not a toxin In the case of the toxins which I have been studying, I would explain their lethal effects on the animal as follows The toxic group of the cell has a special chemical affinity for a certain group of the body cells that control respiration It does not destroy these cells, but throws a certain number of them out of commission, so to speak, and if this number be great enough, respiration ceases and the animal dies However, careful tracing of the respiratory movements, before one commits himself positively to this theory, will be necessary I can not resist the temptation of suggesting the possibility that a cell toxin leaves the nuclein group of the cell intact, while the cell poison breaks up this group, and consequently permanently destroys the cell and renders the formation of an antibody impossible

When the toxin is introduced into the body the injured cell, by virtue of its chemical attraction, repairs its loss by splitting off from the nutritive substances within the range of its chemism groups of "m," and in doing this it splits off more "m's" than it can use, and the excess becomes the antitoxin of the blood serum With this exception it is easily understood why the number of antitoxins that may be formed is practically unlimited in number and why each is specific As group "e" in no two kinds of bacterial cells is identical, the group split off from the body cell will not be identical

In concluding, I wish to express my high appreciation of Ehrlich's theory In my opinion it is the most valuable theory ever presented to scientific medicine and deserves to be ranked with the theory of gravitation and with that of ether, and I think that it is not too much to say that its author has done more to stimulate scientific research than any other man in the profession and it is with much hesitation that I have suggested the modification of Ehrlich's theory set forth in this paper The ideas which I have expressed have grown out of a study of Ehrlich's theory, and if there be in these ideas anything of a permanent value, I hope that they may be considered a tribute to his genius While on the other hand, if my suggestions prove to be without value, they can not in any way, detract from the honor due him whom all workers in this line regard as the master

The details of experimental work done in my laboratory along the lines of this paper will appear in later papers in The Journal

DISCUSSION

Dr James J Terrill, Galveston, Tex —If the cell were rotated and the "m" band as represented in Dr Vaughan's diagram—if that cell is capable of replacing that "m" with, say, one, two or a hundred times, why is it not possible that the body which contains "e" (the colon bacillus, for instance, which still retains, according to this theory, its nucleus separate and intact)—why does not that have the power of replacing this "e" one, two, three and a hundred times, and therefore nothing be gained in this matter? I would like to put that question to Dr Vaughan and hear his explanation of his theory

Dr Joseph Clements, Nutley, N J —We have before us a great problem—that of infection and immunity We have the facts, by the interpretation of which we are to solve this great problem, and these facts are of two kinds—first, the protoplasmic activities of the organism in which the infection or immunity is to obtain, then the other factors (which I may term the external factors), which are the so-called germs and toxins Are we not looking too much at one end of this question? Are we not dealing too much with the external parts of the factors, to the exclusion, somewhat, of the other—the more important—part, which is the protoplasmic activities, so that we can not really and absolutely and correctly interpret the phenomena on this principle and this basis? We shall have to turn our attention a little more to the other side of it—to the protoplasmic activities of the organism in which this great problem is being worked out

Dr Henry Sewall, Denver —If I have rightly understood my studies in immunity, the treatment of bacterial substances with hydrochloric acid is one of the means by which toxins are turned into toxoids I would like to know if Dr Vaughan's researches have not thrown some light on the essential difference between the toxin and the toxoid It would seem as if the difference between poisonous activity and the production of immunity might be cleared up by such work as this

Dr S J Meltzer, New York City—One of the constituent chemical groups of the colon bacillus was designated by Dr Vaughan as hemolytic These groups were obtained after the bacterial bodies were exposed to the chemical action of sulphuric acid Hemolysis can be produced by many different methods For instance, by osmosis, as in the hemolysis caused by water or any hypotonic solution, or by chemical actions, as in the effects of bile acids, etc , or by biologic methods, as in the effects of alien serum In the last case the hemolytic effect is not due to osmosis nor to any known chemical action, it is, so to say, a vital phenomenon I wish to call attention to the difference between the hemolysis of the colon bacillus spoken of by Dr Vaughan and the bacterial hemolysis spoken of by other bacteriologists The hemolytic effect of the tetanus bacillus is a purely biologic phenomenon and is equal in its effect to that of alien serum, while the hemolytic effect of the profoundly disintegrated colon bacillus is apparently only of a chemical nature Dr Vaughan tells us that a colon bacillus is nothing but a chemical mechanism It consists of six definite chemical groups, perhaps more, but the bacillus is nothing but a combination of these groups We know that all living organisms contain a good many chemical groups Does Dr Vaughan mean to convey the view that the colon bacillus consists of nothing else but these chemical groups? Perhaps I misunderstood him But if this is, indeed, his view, then I for one would not be converted to it until Dr Vaughan, or someone else, succeeds in creating a colon bacillus by putting together all the constituent chemical groups without the aid of a living bacillus—were the creation only a very modest colonculus Until then I will be grateful to Dr Vaughan and other eminent chemists for establishing many more definite chemical groups as constituents of living organisms, but will stick to the belief that these organisms possess beside the chemical groups, some other factor which for a great many years to come we will have to designate as vital

Dr Victor C Vaughan—I shall answer as best I may these questions The one about the possibility of the colon bacillus rebuilding itself is an interesting and proper question This is exactly what does happen when the bacillus grows in the body In the animal that is not immune, the colon bacillus builds itself and continues to elaborate poison until it kills

In regard to Dr Meltzer's question, I may say that I am not trying to solve the problem of life I am studying the material of which the colon bacillus is composed The question of the origin of life is too big for me to undertake to discuss I imagine that life is something more than matter, and, as stated before, I am simply discussing the material out of which the cell is built I have used the term hemolysis, not in a biologic but in a chemical sense, and exactly as I understand it has been largely used by Ehrlich and all others working on this subject I can precipitate the hemolysin, wash it free from other substances, put it into the blood and study its action I have certain reasons for believing that there is a toxoid group in the colon cell This point I have not gone into in the paper but hope to do so in a later communication I have formulated the theory which I have offered because some theory is necessary in order to do systematic and scientific work

Dr **Winfield S Hall**, Chicago—I have been very deeply impressed with the character of this work which Dr Vaughan and his associates in his department have been doing for a number of years, and I feel that this Section is very highly favored in receiving from Dr Vaughan so clear a statement of the work that he has done and of the hypothesis on which he is working for future results I can not help feeling that in this work he is really laying the foundation of a broad, scientific basis for the whole subject of toxins and of immunity and immunization I believe that the discovery of diphtheria antitoxin was a chance discovery Several of these discoveries have been made, but the relation of these individual toxins and antitoxins the one to the other has been purely hypothetical I believe that the work of Professor Vaughan and his associates will result in clearing up this whole subject now only hypothetical, and in giving to the world a science of immunization I wish to offer a resolution, not of thanks, but of appreciation Dr Vaughan is not working for thanks, but appreciation helps along a little occasionally, and I move a vote of appreciation to Dr Vaughan and his department for this epoch making work that he is doing

[The resolution was adopted by a unanimous vote]

PRIMARY MALIGNANT ENDOTRACHEAL TUMOR

PRELIMINARY REPORT *

JUDSON DALAND, M.D
Professor of Clinical Medicine at the Medico-Chirurgical College
Physician to the Medico-Chirurgical Hospital
AND
JOSEPH McFARLAND, M.D
Professor of Pathology and Bacteriology at the Medico-Chirurgical College.
PHILADELPHIA

This case is of interest from not less than three standpoints First, that of the physician, because of the importance and extreme difficulty of diagnosis, second, that of the surgeon, because the treatment is purely operative, and third, that of the pathologist, not only because of the rarity of malignant growths in this situation, but because of the histologic structure of this tumor This paper is directed especially to the pathology

Primary tumor of the trachea is exceedingly rare, and according to Scheuer,[1] but 22 per cent of these are primary malignant growths

Sir Morell Mackenzie,[2] after sixteen years of experience, saw but four cases of tracheal tumor, and it is probable that but one or two of these were primary and malignant

Only twenty-eight cases of this disease are reported, most of which were discovered at autopsy in Germany or Austria

In 1882 Delafield[3] reported a case of primary carcinoma of the bronchi, which invaded the trachea to a very slight extent A number of cases of secondary invasion of the trachea by laryngeal carcinoma have been reported A careful search through American medical literature failed to disclose a case of primary malignant endotracheal tumor

History—The patient, a woman, aged 34, married, living in a malarial district, had always enjoyed good health until the present trouble began, although her husband, a physician, observed that she had been rather pale during the past year or two

In the summer of 1903 a slight cough began, uninfluenced by treatment, and in August dyspnea and expectoration were superadded The sputum was thick, tenacious, blood stained and mucopurulent, reaction neutral, and showed, microscopically, squamous epithelium, blood, diplococci, staphylococci, streptococci, but no pneumococci, tubercle bacilli nor yellow elastic tissue A second examination gave similar results and the quantity for twenty four hours was 400 c c There was no fever and these symptoms gradually increased in severity until Nov 27, 1903, when she was seen for the first time

General Examination—The dyspnea was extreme, of the inspiratory type like that observed in laryngeal obstruction Each inspiration was prolonged, labored and accompanied by insinking of the supraclavicular and infraclavicular fossæ and retraction of the base of the thorax. The rate of respiration and pulse was usually about normal

The constant struggle for breath, interrupted by frequent paroxysms of coughing, caused sleeplessness and exhaustion A few bronchitic râles were heard over both lungs, otherwise the examination of thoracic and abdominal contents and urine was negative

Laryngoscopic Examination—This examination, which was rendered extremely difficult by the dyspnea and paralysis of the right vocal cord, showed a swelling in the lower portion of the trachea, the surface of which was the same color as the tracheal mucous membrane This swelling was erroneously interpreted as indicating external pressure on the walls of the windpipe Two fluoroscopic and skiagraphic examinations gave negative results As an absolute diagnosis was impossible, a probable diagnosis was made of a tumor, possibly aneurismal, pressing on the trachea in the region of the innominate artery An exploratory operation was advised, but was declined by the patient (The autopsy demonstrated that this probable diagnosis was erroneous) The prognosis was absolutely unfavorable

Death—A few weeks later aspiration bronchopneumonia occurred, accompanied by a fever ranging from 101 2 to 103 8 degrees F, which disappeared on the ninth day Suffocation and exhaustion, preceded by deep cyanosis, caused death on Jan 1, 1904, seven months after the onset of the first symptoms

Autopsy—The autopsy was performed ten hours after death The brain and spinal cord were not examined, and there was no thoracic aneurism nor tumor With the exception of a tracheal bronchitis the examination of the thoracic and abdominal contents revealed nothing of importance

At or about the lower third of the anterior wall of the trachea was a papillomatous tumor about the size of the distal phalanx of an adult finger, which extended almost to the bifurcation of the trachea and measuring 5x3½ cm This tumor caused extreme stenosis and occupied more than three-fourths of the lumen of the tube.

Immediately beneath this growth were a few moderately enlarged glands about the size of a marrowfat pea, which were firmly adherent to the outer wall of the windpipe This region corresponds to the place where the innominate artery comes in close relation with the trachea, at which point the recurrent laryngeal nerve was compressed by the enlarged glands and inflammatory exudate

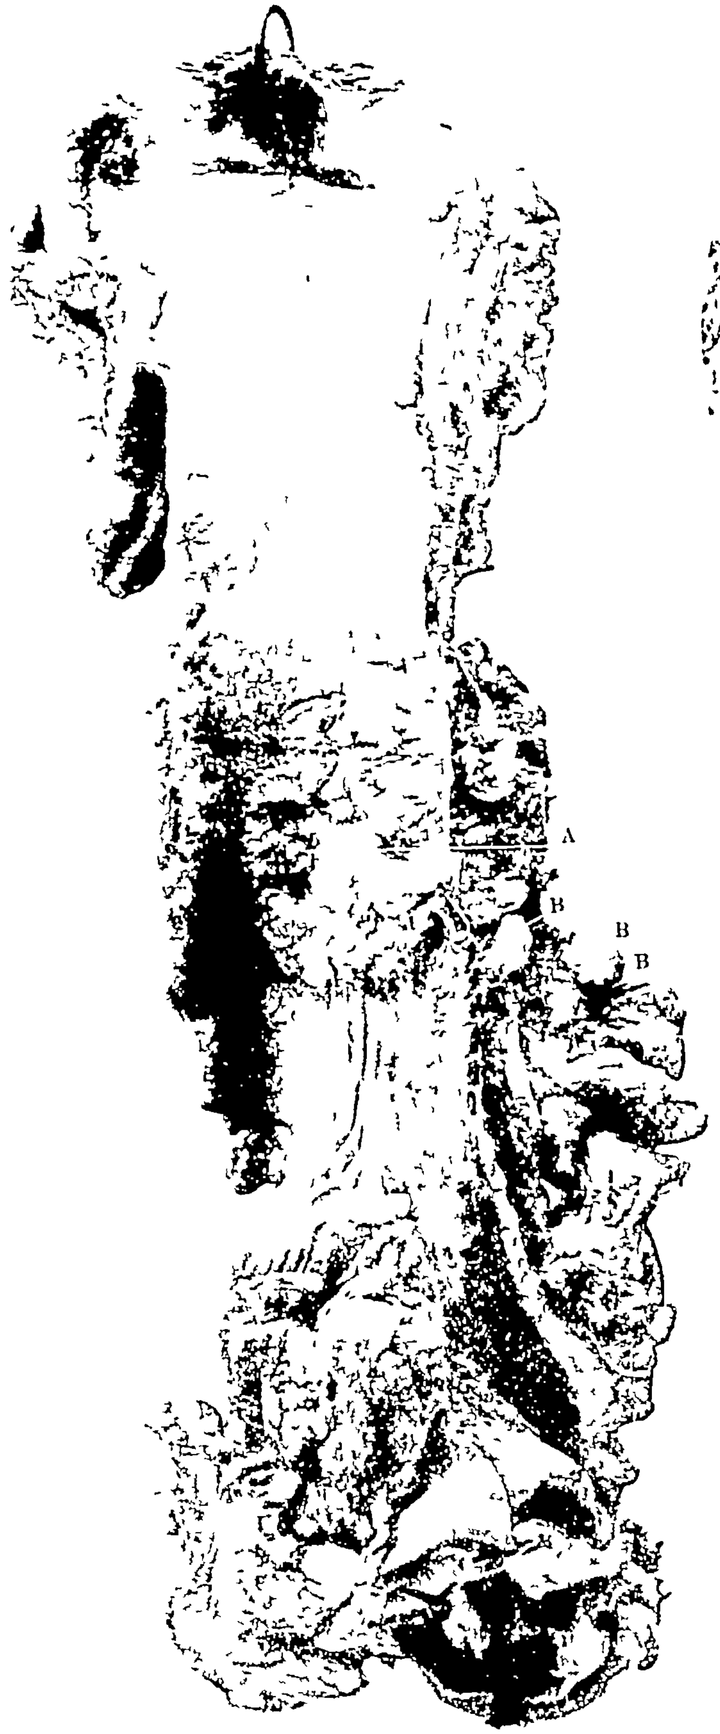
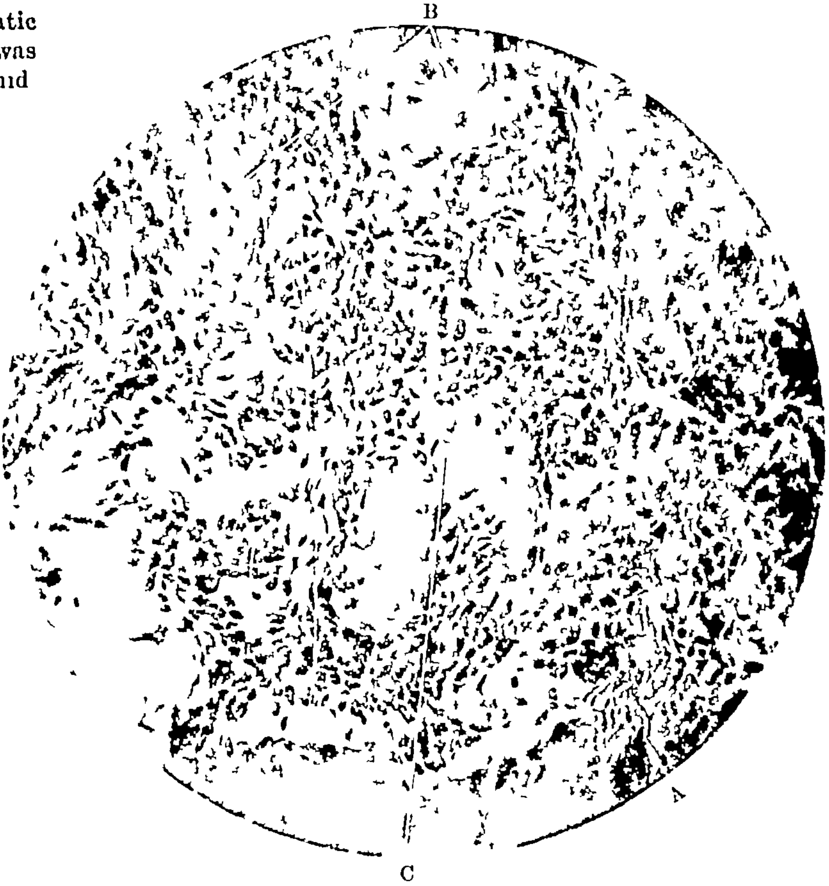
PATHOLOGIC EXAMINATION BY DR. JOSEPH McFARLAND

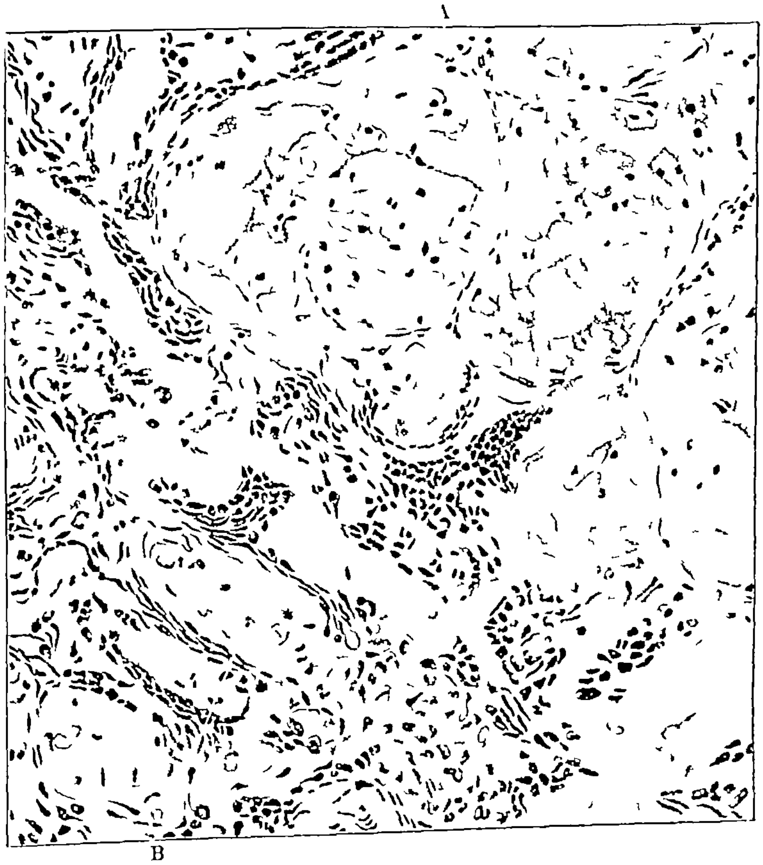
Macroscopic Examination —The specimens submitted for examination consisted of the larynx, trachea, the upper extremities of the bronchial tubes, with the adjacent lymphatic glands and tissues of the roots of the lungs The trachea was opened posteriorly so as to reveal on the anterior wall midway between the cricoid cartilage and bifurcation a fairly well circumscribed neoplasm This formed for the most part a somewhat flattened, tabular swelling, whose greatest diameter was about 5 cm and least diameter about 3½ cm The surface appeared villous when the specimen was first examined in physiologic salt solution, but became slightly roughened



Trachea cut open longitudinally showing the tumor just above the bifurcation Its originally villous character has been lost through the action of the preserving reagents The color corresponded exactly with that of the tracheal mucous membrane (About natural size) A, The tumor, B, lymphatic nodes of which two were infiltrated



Section through the superficial portion of the tumor showing the villous connective tissue prolongations (A) the nests of cells (B) and a peculiar cornified cell (C) (x400)



Section through the base of the tumor showing the disorganizing mucous glands (A) in the upper right hand half of the drawing and the squamous epithelium composing the tumor itself in the lower left hand half of the drawing (x500) Nests of squamous cells (B) after having been placed for exhibition in Zenker's solution

The tumor had the same pinkish color as the mucous membrane of the trachea There seemed to be no ulceration, the right half of the tumor, consisting of two fairly good sized nodes must have considerably obstructed the lumen of the tube during life The borders of the growth were, therefore, slightly elevated and differentiated from the normal tissue. When a section of the tumor and tracheal wall was made, it was found that its extension into the substance of the trachea was accompanied by loss of substance, that the cartilage rings of the organ had disappeared and that its wall had been reduced to the layer of connective tissue The lymphatic nodes about the bifurcation of the tumor were slightly enlarged, and one at least presented small nodes as if from secondary invasion by the tumor, and on microscopic examination this was found to be correct. The nodes thus invaded were immediately beyond the tumor and were adherent to the trachea wall A portion of the esophagus, fortunately that part underlying the tumor, had been removed together with the trachea, and when opened showed no abnormality There seemed to be no connection whatever between the neoplasm of the trachea and the tissues of the esophagus

Microscopic Examination.—Examination of the microscopic section with the hand lens showed that the cartilaginous rings of the trachea were not completely destroyed beneath the tumor, but that the tumor invaded the trachea wall between the cartilaginous rings and partly surrounded them Under the microscope the entire structure of the mucous membrane was disturbed by the neoplasm In the lower layers of the mass were found mucous glands not showing any marked departure from the normal, but these glands seemed to extend upwards into the tumor mass, and as one followed them in this direction their cells became more and more degenerated until rounded openings devoid of cells were occasionally observed.

From the connective tissue of the tracheal wall prolongations extended inward, branching so as to have a dendritic appearance These were covered by layers of epithelial cells of a peculiar flattened spindle shape, the superficial layers of which were in process of active desquamation In the depths of the tumor this desquamation caused the spaces between the dendritic outgrowths to be filled with a seminecrotic mass of desquamated cells The interspaces between closely approximated villi not infrequently contained cells massed together in a manner suggestive of the epithelial pearls of the common forms of squamous epithelioma In these cells various peculiar inclusions may be observed The cells on the terminal branches of the villi desquamate singly and in masses, so that the surface of the tumor presents a very much frayed appearance

As has already been suggested, the invasive nature of the tumor was shown by the metastatic growths in the adjacent lymph nodes, in one of which there was a nodule ½ c in diameter, distinctly circumscribed and corresponding in all its histologic details with the primary growth The situation of the tumor, the peculiarity of the cells of which it was composed, the partial cornification of the cells, suggest that the tumor had developed from an inclusion of esophageal epithelium in the wall of the trachea during embryonal life, and we are lead to believe that this is the true explanation of the origin of the growth

---

The Word Neurasthenia.—The *Lancet*, April 30, begins an editorial article as follows "Invented by Beard, of America, in the 'sixties' to describe and to include a class of nervous affections more common in America than elsewhere, the term 'neurasthenia' has been used with great elasticity," etc. It is true that we owe much of our knowledge of neurasthenia to the late Dr Beard, but he did not invent the word, says the (N Y) *Medical Record* Old Ludwig Kraus defined it in his "Kritisch etymologisches medicinisches Lexikon," the third edition of which was published in Göttingen in 1844 long before Beard dealt with the subject

REGENERATIVE CHANGES IN CIRRHOSIS OF THE LIVER *

W G MacCALLUM, M D
Associate Professor of Pathology in Johns Hopkins University
BALTIMORE.

In the literature and in the text-books of pathology little reference is made to the evidences of regeneration in cirrhosis of the liver It is true that it is stated that regenerative changes are evident in certain cases leading to the production of adenoma-like nodular masses of liver tissue, and there is in general a tendency to regard the bile duct-like structures which occur in the fibrous bands as newly formed and as representing an effort toward the restitution of the liver to its original bulk Especial stress is, however, usually laid on the degenerative changes in the liver cells and the anatomic picture presented by a cirrhotic liver is commonly looked on as the expression of a steadily progressive destructive process

Kretz[1] only, so far as I can see in the literature at my command, has especially emphasized the importance of the regenerative changes in the ordinary type of cirrhosis and the fact that the anatomic condition as found at autopsy is probably the product of numerous attacks of some destructive affection from which the liver has more or less completely recovered He discusses these changes briefly in a variety of conditions in an earlier paper, and in his later communication speaks particularly of the disturbed anatomic arrangement of the liver tissues in cases of advanced cirrhosis and of the consequent obstruction to the circulation His attention is particularly attracted to the masses of liver tissue which he thinks are no longer to be regarded as acini since they have lost the typical architecture of the acini and the typical relation to the blood vessels He states that many of these nodules are without central veins—others have central veins at their edges, while within the nodule the capillaries are so distorted that injections through the portal vein pass more readily to the hepatic veins by way of the fibrous tissue than through their substance, and even that the blood from these masses reaches the central vein by way of the fibrous strands He regards these isolated masses of liver tissue as largely new formed and defines cirrhosis as essentially a combination of focal or localized recurring chronic degenerative processes with regeneration

All of the studies of regeneration in cirrhosis are based on the experimental work of Ponfick, Podwyssozki, von Meister and others, and the anatomic observations of Marchand, Meder, Stroebe, Barbacci and others who have investigated the late results of those destructive processes loosely classed under the name "Acute Yellow Atrophy of the Liver," in which conditions for the study of regeneration almost identical with those produced experimentally are presented

It is well established, as I have also pointed out in a previous paper,[2] that in those cases in which, after extensive destruction of the liver substance, the individual survives for a considerable time, not only is the débris of the necrotic liver substance removed and scar tissue formed throughout the skeleton of the liver thus left without cells, but the specific elements which remain evince an extraordinary power of reproducing themselves, tending by this hyperplasia to replace the lost tissue. This repair takes place according to Marchand in three ways:

[1] Kretz Ueber Lebercirrhose Wiener klin Woch 1900 vol xiii p 271

[2] W G MacCallum Regenerative Changes in the Liver After Acute Yellow Atrophy Johns Hopkins Hospital Reports 1902 vol x.

1. By hyperplastic proliferation of the larger intact remains of the gland parenchyma.
2. By proliferation of isolated liver cell clumps or remains in the region of the most intense destruction.
3. By proliferation of the interacinous gall ducts which, in conjunction with the latter, form new liver cell strands.

Of the cell tubules making up the last group he says elsewhere that they are by no means to be considered as atrophic rows of liver cells, but are doubtless new formed. In their production not only the small interacinous ducts, but also those liver cells which have escaped destruction in the acinus take part. While the first grow from the periphery into the loose meshwork of the acinus, the isolated liver cells in proliferating provide them with new formative material.

In the case reported by me it was possible to support these views in their entirety, with perhaps the exception of the last point. That this process of the combination of sprouting bile ducts with proliferating isolated liver cells could not be seen, was doubtless due to the fact that in that particular case in the area of most intense cell destruction all the cells of the acini were destroyed or so far degenerated that they were incapable of any participation in the regenerative process and regeneration necessarily resulted from a proliferation of the bile ducts alone. I regret therefore that my statement should have been regarded by Professor Marchand as an opposition to his views,[3] since it was merely intended to describe the conditions in a special case.

I have there expressed the view that whenever the highly differentiated liver cells remain the regeneration is simply enough effected by their proliferation. Where, however, they are all destroyed the less highly differentiated but genetically identical cells of the bile ducts proliferate and subsequently become specialized in form and function until they are indistinguishable from liver cells. To what extent then can these principles be shown to be active in cases of cirrhosis?

The material at my disposal consists of those cases of cirrhosis of the liver which were found in the series of 2,300 autopsies which were performed at the Johns Hopkins Hospital, together with a few miscellaneous cases from other sources, in all sixty cases. For the present instances of cirrhotic changes in connection with chronic passive congestion, tuberculosis, syphilis, tumors, abscesses, etc., have been left out of consideration.

The general anatomy of the cirrhotic liver is so universally well known that I need not dwell on it here. The difficulty of making a sharp distinction on purely anatomic and histologic grounds between the generally established classes of atrophic cirrhosis, hypertrophic cirrhosis, etc., is also well recognized, and the clearing up of the processes under discussion may throw some light on it.

Kretz claims that a source of confusion in the study of cirrhosis of the liver lies in the tendency to explain the nodular masses which occur there on the basis of the normal acinus, whereas they are very different, the difference being largely in the loss of their central veins, a process for which he offers no satisfactory explanation.

These nodules vary greatly in size, sometimes forming masses which project above the surface of the liver or stand out sharply on the cut surface, distinct in color and consistence from the surrounding tissue. It is to these very large nodules that reference is especially often made in connection with hyperplastic and regenerative changes in cirrhosis. Often they are composed of very large masses of liver tissue with central vein and radially arranged cell strands in every way like a magnified liver lobule. In other cases, however, they are masses of numerous lobules or portions of lobules, no one of which very greatly exceeds the normal lobule in size. As we proceed to the smaller and smaller nodules there are fewer masses which resemble a complete acinus. Many consist of masses of somewhat atypically arranged cells in which no central vein can be seen. Of course these may be explained as lobules cut tangentially. Others have the central vein situated near to one side or even at the extreme margin, or sometimes one may recognize the central vein embedded in loose connective tissue at a slight distance from the edge of the nodule.

Here the question arises as to what we are to consider the true normal form of the lobule or acinus. Obviously on embryologic grounds the lobule should be the mass of tissue which is drained by the ultimate branch of the bile duct, but mainly on account of the peculiar abundance of connective tissue in the liver of the pig which outlines lobular masses, the highly irrational plan of adopting the efferent vein as the center and index of the position of the lobule has become firmly established. This, however, is justified by the very distinct demarcation of such masses of tissue and by the fact that these masses do behave more or less as individual structures under the stress of circulatory disturbances, etc. If now we inject the hepatic vein with colored celloidin and then clear up or corrode the preparation, it will be found that the vein branches very profusely and at the periphery of the liver there are even found anastomoses between the adjacent branches. Reconstructions of such a liver now show that the lobules are by no means isolated rounded, cylindrical or polyhedral masses with a single central vein, but that the liver tissue really forms a sort of thick mantle for the hepatic vein and its branches interrupted when the vein becomes too large by the approach of another similar mass (Mall). Thus a lobule has a very complicated outline and the areas of tissue which are usually regarded as cross-sections of the acinus are in reality cross-sections of a branch only of the coherent mass which in its entirety answers to the definition of the lobule in this somewhat broader conception. This, as is readily seen, is not fundamentally different from the current idea, but it is of interest in explaining some of the relations seen in cirrhosis. It is also true that in many of the acini there are side branches of the central veins, about which the liver cells are radially arranged, but which do not thereby produce much disturbance of the general outline of the lobule; with the increase of their surrounding liver cells such a system would probably constitute a branch of the lobule.

One may readily convince oneself of the truth of the statement which has been repeatedly made, that in cirrhosis of the liver there may be masses of liver cells as large in cross-section as the branches of the normal acini, which have no central vein and the cells of which are arranged in more or less parallel rows, but not radially, about such a point. Other such masses are found in which a central vein is visible eccentrically placed, sometimes even at the very margin of the mass. Sometimes one can see what appears to be a central vein in the connective tissue adjacent to the mass of liver cells Unfortunately I have had no opportunity as yet to inject the hepatic vein in an advanced case of cirrhosis of the liver, by such a method one would be able to recognize easily all the relations of such branches as had not been obliterated

---

[3] Perzina: Inaug. Diss. Leipsic, 1903.

In the study of the changes after acute yellow atrophy or other destruction of a large part of the liver tissue referred to above, it was easy to reach an obvious explanation of these relations In some instances the lobules were intact, and then after the hyperplastic process has run its course large symmetrical lobules resulted with the central vein in its normal relations Of other lobules half of the tissue was destroyed, only the skeleton of the connective tissue remaining from the other half From such large masses were produced with the central vein at one margin In case only a sector of the lobule remained there ensued the formation of a larger wedge-shaped mass with the central vein at the point of the wedge Finally at any given level, all the cells of the lobule might be destroyed except a group originally situated toward the periphery Then there would arise the enlargement of this mass into a mass of irregular form, the original central vein of which might be situated at some distance in the connective tissue skeleton Now as this skeleton usually collapses to a great extent and becomes overgrown with scar tissue the central vein may become very inconspicuous or even completely obliterated, and hence the appearance of lobules or nodular masses without any central vein

Precisely this process can be demonstrated in most instances of cirrhosis of the liver more easily and plainly in the coarsely nodular forms than in the finely granular or smooth cirrhotic livers

To form a clear idea of the conditions which result from such a process single sections of the liver will not suffice The nodules which appear to be entirely isolated masses of liver cells in a single section usually prove in serial sections to be merely the outlying spurs of other ramifying, irregular conglomerates Really isolated groups of cells do occur but are relatively rare

From the study of serial sections one gains the idea that instead of the normal smoothly outlined, branching acini we have here acinoid masses with extremely irregular gnawed-out outlines, the erosions being often so deep as to expose on many sides the branching central vein or even so deep as to completely cut off portions of the lobule

Were the process to stop there this explanation would be much more evident than it is, on the contrary, regenerative hyperplastic changes occur in these injured lobules so as to restore to a great extent their rounded outlines and to bring them back to their original bulk or even to a bulk greater than that of the original lobule This occurs expansively in the remains of the liver tissue, and although if one were to model such a mass it might in outline roughly resemble the model of a normal acinus, the introduction into the model of the central vein would at once show what an extremely irregular eccentric structure such a rehabilitated lobule really is Instead of the branching central vein with its uniform mantle of liver cells we would find the vein quite exposed in places, surrounded by cells in other places and in still other places large, irregular clumps of cells might be applied to one side of it or throughout some distance be separated from it entirely

Reconstructions from hardened livers without any injection of the hepatic veins are, therefore, of relatively little value, but when a suitable case presents itself it will be possible to illustrate this point very graphically by means of a proper wax model

The radial measurement of these nodules must also afford an indication of the increase in size over the normal This could be effected best by the measurement of such a model as mentioned above in which one could be sure of measuring the line at right angles to the central vein where the lobule has its greatest radius Only the extreme measurements would be of value, for elsewhere one could not be sure whether he were dealing with the original thickness of the lobule or with the thickness resulting from primary atrophy and secondary hypertrophy The extreme measurements found in serial sections, however, where one is careful to measure the real radius (not an oblique radius) at its greatest length, will practically correspond with this, and while it must vary greatly in different cases (being often greatest in the cirrhosis of children, which is notoriously coarsely granular owing to the active power of regeneration in children), it will at least prove that enlargement has occurred So, for example, while the average radius of the lobule (i e, thickness of the mantle of cells about the central vein) in a number of normal livers was found to be about 66 mm acini were found in advanced cases of cirrhosis which measured from central vein to periphery 1 00 mm or more

Positive evidence of hyperplasia are abundantly present in these acini Cirrhosis is of course, a chronic process of long duration so that it is not surprising that in most cases mitoses are seldom seen From the study of the early stages, however, it is seen that mitosis is then extraordinarily abundant in the liver cells and that it occurs as an almost immediate sequence of the destruction of the rest of the liver cells Such necroses destroying a portion of lobule occur, as is well known and as Dr Opie has recently emphasized, as the result of a great variety of infections and toxic processes, and in one such case at least which Dr Opie has brought to my notice I was able to find numerous karyokinetic figures in the peripheral parts of the lobule, while the cells of the central part, although necrotic and devoid of nuclei were still present in almost their normal position and arrangement.

Similarly, in another case which I must regard as an early stage in the production of cirrhosis of the liver the cells throughout the remnant of the lobule, even after a certain amount of scar tissue had been formed in the periphery, were in a state of active division

Ponfick showed, as has been mentioned in the previous paper referred to, that although mitoses were abundant in the early stages after the extirpation of portions of the liver, they were represented in the later stages only by such conditions as are almost constantly seen in cirrhosis and in the regenerating liver after acute yellow atrophy, i e, the presence of two or more nuclei in a single swollen cell, the occurrence of large, clear cells with convex outline, etc Further, one may frequently observe side by side in such a mass, cells which retain the usual form and sometimes deep pigmentation, and cells which are much larger and plumper and are relatively free from pigment These latter may even form masses of thick columns so arranged in a rounded form as to compress by their expansile growth the neighboring nonproliferating liver cells One can scarcely escape the conclusion that these are new formed cells

If now we turn from the recognizable liver tissue to the remaining tissue we find conditions about which there is perhaps more ground for controversy. As to the significance of the fibrous tissue there has been much discussion, but the weight of opinion is now against the idea that it constitutes a primary new growth of connective tissue which by its contraction compresses the liver tissue and causes the destruction of that tissue, which is apparent in any advanced cirrhosis. Briefly, examination of a section of almost any advanced coarsely granular cirrhosis will show at once that part of the connective tissue is the pre-existing fibrous skeleton of the liver, for it is frequently easy to make out the collapsed framework of the lobule from which the liver cells have been destroyed and eliminated, part of it is the tissue which originally surrounded the vessels and bile ducts and part of it is new formed in the sense that a scar appears to take the place of more highly specialized tissue which has been destroyed. That this scar may by its later contraction constrict the highly specialized elements that are enclosed within it can not be denied. Beside these things which we have described there are the bile ducts and bile duct-like structures whose rôle in cirrhosis has given rise to the most active discussion. The literature on this question has been so well reviewed by Meder and others who have considered the similar or identical structures in connection with the regenerative processes following acute yellow atrophy, that it is not necessary to repeat it here. It may be well, however, to review briefly the anatomic conditions as exhibited by our series of cases.

It has been shown that the disturbance in the structure of the liver indicates that a destructive process, affecting chiefly the peripheries of the lobules, but sometimes extending so deep as to involve the whole diameter, leaves behind it a collapsed skeleton which soon becomes almost indistinguishable from the pre-existing connective tissue about the portal spaces and which, with the coincident growth of new scar tissue, is quite merged into the wide bands of fibrous tissue which run through the liver. This in itself would bring about a concentration of the pre-existent bile ducts on the disappearance or collapse of the liver lobules. The bile duct-like structures sometimes present only in small numbers, sometimes very abundant, lie for the most part in this tissue, and it is naturally of interest to us to know whether they lie in the skeleton of the old lobule or not. Since, however, the greater part of the fibrous tissue coincides with this, or is new formed, we may regard this relation as very close. The point of dispute is, therefore, whether the structures are to be interpreted as compressed or otherwise modified liver cells undergoing a retrogressive process, i. e., the remains of the injured constituents of the lobule, or as newly-formed strands arising from the bile ducts, or possibly as a combination.

Now the condition actually found is about as follows: Where the lobule is relatively intact there are relatively few bile duct-like structures at its margin communicating with the liver cell strands, as in the normal liver. Where the erosion or dismantling of the lobule has been extensive there is a wider strand of fibrous tissue and the bile duct-like channels are numerous, and one may distinguish the main bile ducts, which are unmistakable, and are lined with cylindrical epithelium. Many of these are obviously elongated and even spirally twisted and branched. Beside these there are smaller channels with narrow lumen and a lining of cubical or flattened cells. These, too, branch and sometimes anastomose and many of them are continuous with the liver cells of the adjacent side of the lobule. When the destruction of the lobules has been very widespread and the fibrous band is very wide, it is frequently found that no such connection takes place, but another change is substituted, which will be described later.

It is perfectly conceivable, therefore, that the portions of these strands in connection with the liver cells for such a distance as would correspond with the remainder of the radius of the old lobule, may represent compressed or modified liver cells, and it is not possible to bring absolute proof in all cases that this is not so. Frequently, however, the ducts are very much longer than could be accounted for in this way, and it will be decisive in this regard to search for evidence as to whether their cells are in a stage of degeneration or retrogression, or in a condition of progression or proliferation. Sometimes the strands of fibrous tissue are so narrow and the ducts so short that this latter point alone could yield a decision.

In a case which presented itself recently at the Johns Hopkins Hospital the state of the liver seems to throw some light on the process.

CASE 1.—Autopsy, 1829. This was the case of a man who died after a brief illness, in which icterus, delirium, etc., were prominent symptoms. The liver was pale greenish yellow in color, quite smooth, and on section showed the lobules very distinctly as slightly prominent, rather opaque, greenish yellow masses. The consistence of the liver was slightly increased, but there was, macroscopically, no distortion of its structure. Microscopically, there was found to be a slight irregularity in the form of the lobules, with a moderate increase in the periportal connective tissue. The liver cells in the lobules were not homogeneous in appearance, but some, chiefly the more peripheral, were greatly enlarged and so loaded with fat that the protoplasm appeared as a delicate web. The nuclei were all well preserved. The remaining cells were small and flattened, and frequently arranged in double rows so as to present a rather wide lumen. Their protoplasm stained rather deeply and was not granular to the degree seen in the normal liver. In both of these types of cells abundant mitotic figures could be seen. In the connective tissue strands, but continuous with the liver cells, there were numerous ducts, readily distinguishable from the duct like strands of liver cells in the lobule. In these, numerous mitotic figures were found. The bile ducts proper were not especially altered, but occasionally mitoses were found in their cylindrical cells.

In this case, with the typical formation of bile duct-like strands in the connective tissue, it is clearly seen that these structures are by no means degenerative in character, but are due to an active production of new cells by an intercalated mitosis. In the advanced cases of cirrhosis such distinct evidence of proliferation of the cells of the ducts is usually not to be found but the great length and tortuous branching which often characterizes them, and the good state of preservation of their cells makes it practically certain, in the light of this case and of the cases of regeneration after acute yellow atrophy, that they are due to a proliferative process. Their lack of resemblance to the elongated red staining cells so familiar as the result of compression of the liver by tumors or abscesses need scarcely be mentioned.

While these strands must be regarded as progressive in character we can not be sure that they are exclusively derived from the bile ducts. Where the case can be observed in the early stage, as in the one described, the continuity of the duct with the liver cells is often to be made out, and even when this continuity is broken through, as it must be in most instances, no greater difficulty in the reinstatement of the continuity need be anticipated than in the fusion of the edges of proliferating epithelium which approach one another to heal over an ulcer in the intestine or a wound in the skin

In the case described above there was, further, the modification in the liver cell strands, which produce an appearance something like that of the bile ducts, but since these cells were in active mitosis they could not be compressed or degenerating On the contrary, it seems probable that they should be regarded as a reversion to a less highly specialized and temporarily nonfunctional form for purposes of reproduction, and in all probability in a later stage such cells would have regained the ordinary appearance of liver cells A similar modification in the liver cells was pointed out to me by Dr Opie in another case, in which, as a result of appendicitis with generalized acute peritonitis, there was widespread necrosis of the central portions of the lobules In this case, in which death occurred so soon that the necrotic cells were all in their original position, many strands of the intact liver cells within the lobule had assumed the form described in the other case, although there was nowhere any proliferation of connective tissue and I was able to find abundant mitotic figures among these intact cells of the lobule

Thus, while we can not say absolutely that the injured liver cells in a compressed state do not constitute some part of the duct-like strands found so abundantly in the wider bands of fibrous tissue, the weight of evidence is entirely in favor of the idea that these are the result of intercalary proliferation by mitosis in the bile ducts or, perhaps, in peripheral portions of the liver cell strands which remain in continuity with the pre-existing bile duct. Where the liver cell strands are interrupted or destroyed, partial or complete collapse of that portion of the lobule results, but whatever cells are left in the direction of the large bile duct proliferate and reinstate if possible, the connection with whatever cells remain in the lobule If liver cells are left in connection with the duct they proliferate with the same end in view

This brings us to another point, perhaps the most important, in showing this proliferative power of the bile ducts in the older cases of cirrhosis Often the connection with the liver cells is not reinstated and the bile ducts are left ending blindly in the connective tissue Such ducts may often be shown to give rise to isolated bulbous masses of cells which gradually acquire the characteristics of highly specialized liver cells That they are newly formed is shown by their form, their fresh appearance, and by the lack of pigment frequently found in the adjacent old liver cells Further, it is interesting to note that one may be certain that they are actually formed from the bile duct epithelium and not merely isolated from the neighboring lobule by the fact that specialized pink-staining liver cells may be found not only in the bulbous extremity, but also intercalated singly among the ordinary cells of the ducts These are therefore, in every way like the bulbous sprouts which are described in the case of regeneration after acute yellow atrophy, and indicate very clearly not only that the so-called newly formed bile ducts really are newly formed bile ducts and not compressed liver cells, but that they possess a very considerable power of producing new liver tissue

All of these processes taken together show that we must regard the cells of the bile ducts and the liver cells as identical and equivalent as far as regeneration is concerned, and that while the liver cells are specialized for functional purposes, they are perhaps a little more ready but no more potent in the reproduction of new liver cells than the epithelium of the bile ducts It is, therefore, of little moment to determine whether doubtful cells are liver cells or bile duct cells, the essential point in this study is the proof that these cells are proliferating and not degenerating

Of the degenerative changes which are in progress throughout the cells of the lobules and of the inflammatory reaction so frequently seen in the intervening tissues I shall not speak Nor of the somewhat unsatisfactory classification of the forms of cirrhosis on anatomic grounds, although the idea is of interest that the difference between the hypertrophic or intralobular form of cirrhosis and the annular atrophic or portal cirrhosis lies in the distribution of the necrotizing process which affects the liver cells and which, as Dr Opie has recently emphasized, depends so largely on the circulation of the lobule

CONCLUSIONS

In conclusion we may state that in the ordinary type of interlobular cirrhosis there is a primary destructive process leading to the disappearance of portions of the cell mantle surrounding the central vein of each lobule The framework of the lobule persists but usually collapses, and there is produced an irregular lobular mass in which the central vein is in places left more thinly covered by the radial strands of liver cells, or even completely exposed and surrounded only by the connective tissue framework The remaining liver cells proliferate rapidly by mitosis and generally increase the size of the portion of the lobule which is left. In this process they sometimes assume temporarily almost the form of bile duct cells The connective tissue bands which run through the liver and separate these irregular hypertrophied remains of lobules consist of pre-existing connective tissue together with some which is newly formed Numerous bile duct-like canals course through these bands and it is thought that these are produced by proliferation from the pre-existing bile ducts The degeneration of compression of liver cells in the production of this appearance is not thought to be of importance That the canals are composed of proliferating cells is shown by reference to a fresh case in which mitoses were abundant in their walls and by the fact that they frequently sprout out to form isolated bulbous masses of new liver cells The bile duct epithelium and the liver cells are shown throughout these processes to be equivalent so far as the regeneration of the liver tissue is concerned

The anatomic picture presented by a cirrhotic liver is, therefore, usually one in which the regenerative processes are the most striking, the destructive process being sometimes evident, sometimes entirely past and represented only by the widespread scars

Cirrhosis of the liver may be defined as a chronic disease in which destructive processes, probably often repeated, result in a loss of the functional liver tissue immediately followed by the formation of a scar, the healing process, and later by an attempt at the restitution of the liver to normal by regenerative processes

DISCUSSION

Dr. Felix Adler, New York City—At a very early stage in the experimental cirrhosis of the liver is seen the proliferation going on in the interior of the bile ducts—larger bile ducts, common smaller bile ducts down to the very minute ones—where no liver cells could possibly go The proliferation of epithelium is followed by the widening out and distortion of the basilar membrane and finally the sprouting into branches This occurs at a very early stage for in stance, in that form of experimental cirrhosis which can be induced by the feeding of tobacco, and it bears out Dr MacCallum's theory very thoroughly that at so early a time, when the cirrhotic condition—when the affection of the interstitial tissue—is progressing and is at a very early stage, the bile ducts begin to sprout and proliferate

Dr E Libman, New York City—Some years ago I saw the liver of a child supposed to be suffering either from sepsis or hypertrophic cirrhosis, with fever, the entire period of observation only extended (so far as could be determined) over four or five weeks, and it turned out, at the postmortem, to be a case of sepsis, with abscesses of the kidneys It was interesting to know that in that liver there were in five weeks an increase in connective tissue, and many of the changes which Dr MacCallum has pointed out, it is particularly interesting because Dr MacCallum mentions that the changes can come early

Dr Joseph McFarland, Philadelphia—Did I understand Dr MacCallum to say that he thought the changes in cirrhosis of the liver were primarily necrotic and secondarily productive, or the reverse?

Dr Walter L Bierring, Iowa City—It would seem to me that we might include in these regenerative changes, referred to in connection with cirrhosis, also that condition known as cirrhosis carcinomatosis, which is a sort of adenomatous hyperplasia taking place in a cirrhotic liver There is a definite new growth of cells which resemble hepatic glandular cells, and frequently take on an atypical growth, subsequently undergoing a certain necrosis or fatty degenerative change and presenting to the naked eye yellowish white or softened areas in the cirrhotic tissue The term "carcinoma in cirrhosis" or cirrhosis carcinomatosis is usually applied to this regenerative process

Dr W G MacCallum—Although I have not paid special attention to the forms of cirrhosis resulting from biliary obstruction, the anatomic conditions in those cases which occurred in our series have been practically the same, with the exception of the addition of the continued inflammation about the bile ducts The hypertrophic or intralobular cirrhosis may perhaps be explained in the same way, excepting that there the cell's destruction has occurred diffusely throughout the lobule, leaving scattered cells from which regeneration occurs In answer to Dr McFarland's question I feel quite convinced that cirrhosis of the liver is not due to a primary growth of connective tissue, we must, with Ackermann, regard the cirrhotic liver as a condition in which a primary destruction of the liver cells has been followed by scar formation Dr Adler's observations seem to me to correspond very closely with what I was able to observe in the case of which I have spoken as an early stage of cirrhosis, and in which in the delicate bands of fibrous tissue new bile ducts in the form that Dr Adler has described, were found With reference to Dr Bierring's remarks I may refer to the paper of one of our students[1] wherein was expressed the idea, really suggested at first by Weigert, that in all probability the cirrhosis of the liver had been the result of destructive and degenerative changes, of healing, and of a subsequent regenerative process, which in Weigert's phrase had overstepped the mark and had gone on to the formation of a true tumor which could produce metastases I have been particularly interested in the early appearance of these regenerative changes to which Dr Libman refers The necrotic liver cells may still be present where abundant mitoses in the intact cells are visible Quite the same thing I think must be familiar to you all in the cases of acute nephritis in which the destruction of many epithelial cells stimulates the production of mitotic figures in those that are left, while, although regenerative changes are certainly present in the chronic nephritis, one is no longer able to find mitotic figures in such kidneys

Bartholin's glands are named for Thomas Bartholin, a Danish physician, who was born at Copenhagen in 1619 and who died in 1680

HEART DISEASE AS AN OBSTETRIC COMPLICATION *

C S BACON, M D

CHICAGO

For many years heart disease has been recognized as an important disturbing complication of pregnancy, labor and the puerperium, while on the other hand, careful attention has been directed to the deleterious influences of pregnancy, labor, etc , in the causation of heart disease This subject has furnished several interesting pathologic questions that are not yet solved, and some questions of management are not yet agreed on I do not hope to add new facts, but especially to direct attention to a few points in the management of this complication that are somewhat frequently overlooked

The term heart disease is a broad one, and of course embraces many different pathologic conditions It might be of advantage to separately consider some of these different conditions, and especially to distinguish between diseases of the myocardium and those of the endocardium However, in a general paper, we may adopt the usual custom of considering together all these conditions

Heart disease may arise and develop during the pregnant or puerperal state, and be due to it, or it may have existed previous to pregnancy, and influence the course of pregnancy or labor, or be itself influenced by them An example long recognized of heart disease arising during the puerperium is furnished by cases of endocarditis resulting from puerperal infection Another condition less known is that of myocarditis resulting from the toxemia of pregnancy A parenchymatous degeneration of the myocardium is a common and characteristic finding in postmortem examinations of women dying of gravidal or puerperal eclampsia Careful study of the heart and circulation during an attack of eclampsia confirms the belief that myocardial degeneration is a common condition in eclampsia, and also probably in the large number of cases of eclamptogenic intoxication when convulsions do not supervene The lesion is of all degrees of severity from a slight cloudy swelling to a very serious fatty degeneration Corresponding to the anatomic changes the symptoms are from those of a slight disturbance of the pulse on exertion to the most serious circulatory disturbances consisting of general edema, and especially edema of the lungs coughing and spitting blood, nausea and vomiting dyspnea and palpitation The frequency of this condition, if it corresponds to the frequency of the disease, is several times as great as that of eclampsia, being found perhaps, in 1 per cent of all pregnancies

Fritsch and Loehlein have also called attention to the fact that a systolic murmur heard over the base of the heart and propagated along the vessels is found very frequently in the puerperium and occasionally during pregnancy It resembles in some ways the murmurs of anemia and chlorosis, but its mode of production and its significance are not determined

In this connection a word may be said concerning the much-debated question of hypertrophy and dilatation of the heart during normal pregnancy First Larcher and some others found, in postmortem examinations of women dying in labor, that the weight of the heart is greater than in case of the non-pregnant women These

* Read at the Fifty fifth Annual Session of the American Medical Association, in the Section on Obstetrics and Diseases of Women and approved for publication by the Executive Committee Drs J H Carstens A Palmer Dudley and L H Dunning

data have been questioned, but more carefully made examinations have shown some increase in weight of the heart in pregnancy The efforts of Ducrest and others to measure the thickness of the heart walls are less convincing in the results, because of the great differences in the amount of contraction of the heart muscles and the resulting differences in the thickness of the walls

Duroziez demonstrated an increased area of heart dullness in the latter part of pregnancy which corresponds to the shadows shown in the Roentgen pictures recently made and published by von Rosthorn These findings, however, do not prove an enlargement of the heart, but rather such a change in its location in reference to the anterior chest wall as to bring more of it in contact with the wall Fritsch has held that the heart is not hypertrophied, but rather slightly dilated to accommodate a greater amount of blood

The question is intimately related to the physiologic problem of the change in the circulation during pregnancy and labor Has the heart more work to do during pregnancy? The amount of work to be done by the heart depends on the amount of fluid to be kept in circulation and the resistance of the tubes or blood channels Gescheidlen found in dogs some increase in the amount of blood during pregnancy A more important element than the quantity of blood is that of the resistance in the tubes or vessels

Several ways in which the resistance is probably increased during pregnancy have been suggested by different writers Spiegelberg held that the introduction of the uteroplacental circulation caused a considerable increase in the work of the heart Lahs then showed that dividing the current, as was done by introducing new or additional channels, would rather decrease the resistance and so the work of the heart Other ways of increasing the resistance were then considered The pressure on the abdominal aorta by the enlarged uterus was one The increase in abdominal pressure, due to the growing uterus, was another The obstruction to the pulmonary circulation and disturbance of diaphragmatic respiration, was a third That these may be elements in the problem seems to admit of no doubt There is however, one cause of increased resistance that has, so far as I know, been generally neglected, but one that may be at times of more importance than all others, that is, the splanchnic congestion that is characteristic of pregnancy, and probably dependent on a vasomotor agent that may be due to the toxemia of pregnancy

An elaboration of this theory would require the entire time of a paper, and can not now be attempted In its favor only one very suggestive fact will be recalled an early and a constant symptom of pregnancy is congestion of the genital region with a corresponding anemia of the surface of the body This condition is allied to that of chronic shock, where as we know the splanchnic reservoir is overfilled and other portions of the body are relatively anemic In such a state the contracted superficial and extra splanchnic vessels furnish an enormous resistance to the blood current, and so greatly increase the heart work This disturbance in the circulation is one of the first and most striking phenomena of pregnancy, and must be due to it What more probable than that it, like the nausea and vomiting of pregnancy, the kidney of pregnancy, gravidal neuritis and eclampsia is a symptom of pregnancy intoxication

If this be a factor in the increase of vascular resistance or of the heart work, it will evidently vary much in importance, according to the degree of intoxication in individual patients Where the elimination is poor, as in cases of renal disturbance, the intoxication will increase, and consequently the vascular resistance

The conclusion that may be drawn from the work that has been done in the study of the effects of pregnancy on the heart is that there is generally a slight increase in the resistance due to a number of factors, and to the work to be done which leads to a slight hypertrophy of the normal heart Occasionally the resistance is much increased, and in addition there may be a direct poisoning of the heart muscle by the toxemia of pregnancy The myocardial degeneration thus produced is much more important than is commonly held This pathologic change in the myocardium with the endocarditis produced by puerperal infection constitutes the pathologic changes in the heart disease, due to pregnancy and the puerperium

A heart previously diseased is, of course, more apt to be injured by pregnancy and labor than a normal heart Because we know so little clinically about chronic myocardial changes, we have in mind chiefly heart disease due to valvular lesions Whether the lesion be mitral, aortic or tricuspid, and whether it results in stenosis or regurgitation, or both, the heart is more apt to suffer from increase of work produced by any of the modes of resistance to the circulation The degree in which it suffers varies greatly, depending, not only on the condition of the heart, but also on the importance of the disturbing factors When there is a lack of compensation in the non-pregnant state the strain on the heart will certainly be very great, and may lead to irreparable injury, but if perfect compensation apparently existed before pregnancy, it may be broken down The date when the disturbance begins depends on what factors are most important in increasing the heart work If the toxic agent manifests itself early, perhaps causing a marked degree of nausea and vomiting, the cardiac weakness may be early apparent, perhaps to disappear later under appropriate management The toxic agent may, however, show itself later in conjunction with renal insufficiency Here the distension of the abdomen may co-operate to increase the resistance of the circulation

Pregnancy is apt to cause several kinds of injuries to a diseased heart It may weaken an already overstrained heart muscle or lead to its degeneration, it may also cause a renewal of an old or latent inflammation Of course, both of these consequences may follow as an effect of pregnancy Which is more common or more important is difficult to say

All of the sequelæ of heart disease may be found developing rapidly during pregnancy General and pulmonary edema, dyspnea, bronchitis, palpitation and gastric disturbance are among those most important from a prognostic standpoint In some cases interference with general nutrition will come to be of great significance Rarely death may occur before labor begins

With the commencement of labor special dangers arise If the heart has suffered much during pregnancy and the symptoms of secondary complications have already become threatening, the outlook may be serious But even where there have been no marked signs of cardiac insufficiency a sudden and perhaps fatal collapse is not impossible In the first stage the contraction of the uterus in itself does not, perhaps, increase the vascular resistance, but it is not unlikely that the vasomotor mechanism is disturbed so as to create more work for the heart Moreover, individual voluntary efforts at bearing down cause an increase in abdominal pressure, just as in the second stage, and thus markedly increase the heart labor It is in the second stage that the greatest danger arises The powerful contractions of the abdominal muscles, which in a healthy person may produce a marked cyanosis of the head and chest, may overcome a diseased and weakened organ, and sudden death result

With the completion of labor it might be thought that the dangers are past This, however, is found not to be the case In the casuistic we find many instances of death occurring from a few hours' to a few days' postpartum Much discussion has taken place concerning the conditions which are responsible for these deaths While some have thought that the sudden filling of the venous system leads to distension of the right heart others have held the opposite view, namely, that the sudden emptying of the abdomen leads to overfilling of the abdominal vessels and a resulting deficiency of blood in the heart It is not unlikely that there remains after the emptying of the uterus a high degree of vascular resistance, which continues to impose too much work on the weakened heart, and to which it finally succumbs in spite of the comparative relief that it must get at the completion of the second stage of labor

Additional dangers arise later in the puerperium The condition brought about during the latter part of pregnancy by the disturbed circulation and the respiratory and digestive complications favor local infection and its extension if there be any contamination If infection can be avoided there are still digestive disorders and the kidney disturbance to complicate the puerperium and make it a long and tedious convalescence

When we now turn to consider the effect of a pre-existing heart disease on pregnancy, we find the most common and chief disturbance to be an interruption of the pregnancy This interruption may occur at any time, but most frequently in the third and fourth months It is no doubt due generally to disturbance of the placental circulation, which may frequently be attended with hemorrhage On account of the imperfect placental circulation and the imperfectly oxydized and purified blood, the fetus may suffer and eventually succumb inside the uterus

As there is little or no reason why heart disease should cause sterility, it is probable that the frequency of heart disease in pregnancy corresponds to its frequency in all childbearing women Demelin found heart disease in about 1 3 per cent of all pregnancies Vinay found the frequency to be 2 per cent If 1 5 per cent represents the number of cases of pre-existing valvular heart disease, we must remember that nearly as many cases of myocardial disease arise during pregnancy Many of these cases cause few symptoms and may be overlooked, unless a routine examination of the heart is made in all cases

CARE OF THE PATIENT

In the management of this complication, if the patient be seen early in pregnancy, the first question that arises is, shall the pregnancy be allowed to continue, or should an abortion be induced? If the valvular lesion be accidentally discovered in a patient who has perfect compensation, and is perhaps ignorant of her condition, the question of inducing abortion could not be raised She should simply be carefully watched, and if complications arise, she should be informed of her condition But if at first the patient knows her state, and if there are signs of disturbed compensation, the question can not be ignored If the patient should be very anxious to have a child and object to the induction of premature labor, she should be fully informed of the danger of the occurrence of a spontaneous abortion, the risk of increased injury to the heart, and the danger from secondary complications, and even death The plan for the conduct of pregnancy should then be mapped out

The patient should be required to give her promise to adhere to all details in this plan and co-operate with the physician in every way When the circumstances of the patient will not admit living up to an ideal plan, such modifications must be made as are necessary, but the physician's responsibility is satisfied only when he presents to his patient a complete statement of all the facts in the case

If the circumstances of the patient do not allow her to undertake to follow a course of treatment that promises a successful carrying of the fetus to term, or to viability, and if she wishes an abortion performed to save herself the risks of the pregnancy, then the physician has a most difficult question to decide—the necessity of an operation He must from the histories of previous pregnancies learn the probability of a spontaneous abortion and from the anamnesis and the physical examination determine the condition of the heart and its probable resisting and latent forces The determination of the location and kind of murmur is of minor importance The condition of the pulse, its variation when the hand is raised above the head, the change in the heart action by change of the position of the patient the existence of complications, such as edema and gastric and renal disease, are among the important symptoms and conditions that determine the prognosis and the decision of the physician as to operative interference

When an operation is decided on, it should be done at once Waiting for a spontaneous abortion is not advisable, as it promises no safer outcome than a properly performed operation and leaves the patient exposed unnecessarily to the risks of pregnancy The mode of operation does not differ from that which is employed for other indications If the pregnancy be not advanced beyond the sixteenth week rapid dilatation of the uterus and removal of the egg under ether is the safest method, because quickest and attended with the least danger of infection With proper precaution, ether may be given to a patient with heart disease without fear Between the sixteenth and twenty-fourth to twenty-eighth weeks dilatation of the cervix with a tent or bag must precede the removal of the egg

If the attempt to carry the pregnancy to term is decided on, one of the first questions to engage the attention is the prevention of spontaneous abortion Mueller states that abortion occurs in about one-fourth of all cases of pregnancy complicated with heart disease In severe cases the frequency of abortion is undoubtedly much greater Slight strains or injuries, overexertion wearing a corset and other conditions and circumstances that would have no bearing in a case of normal pregnancy here lead to slight uterine hemorrhage on account of the venous congestion and disturbed placental circulation Hence anything that can act as an etiologic factor should be foreseen and avoided The slightest indication of uterine contraction should be noticed and stopped by appropriate means The patient should be instructed in the meaning and importance of all the signs of the beginning of uterine contractions, the backache, the heavy feeling in the pelvis simulating menstrual molimina, hardening of the uterus, etc At the first appearance of these symptoms she should lie down and send notice to her physician

For the prevention of the uterine disturbances which precede and cause the separation of the egg, as well as for stopping the uterine contractions, the best thing to do is for the patient to keep a horizontal position, as in this position the congestion of the uterine vessels due to gravity is best avoided In severe cases it may be necessary for the patient to keep this position most of the time of gestation It is of use for other reasons The work of the heart is thereby much lessened The work of the digestive organs may be lightened, for the amount of food required by the body is very much less when the body is at rest and protected from loss of heat Hence rest in bed in the horizontal position comes to be the most important factor in the management of heart disease in pregnancy

It is, however, an agent that must be controlled A woman can not lie in bed seven or eight months or even seven or eight days without suffering from lack of exercise The blood and lymph circulation is much dependent on the muscular contractions, without which there is a stagnation, a deficiency in secretion and an auto-intoxication that leads to malaise and disturbed nutrition To avoid these harmful effects of inactive rest, a system of bed exercises and regular daily massage should be inaugurated The details of such a system can not be elaborated here

When uterine contractions indicate that the danger of abortion is imminent, we must supplement rest in bed with sufficient doses of morphin or codein to stop them Sometimes it is necessary to continue the use of morphin for a considerable period When it is necessary to use this drug, it is well to counteract its harmful effect on the intestinal functions by giving salines or other proper correctives

DIET

Aside from measures to prevent abortion, the care of pregnancy includes such dietetic, hygienic and medicinal management of the circulatory, respiratory, excretory and digestive systems as is necessary to keep them in the best possible condition The food should be easily digestible and assimilable and carefully regulated as to quantity Too much food throws unnecessary work on the eliminating organs, and may be a source of great danger In the latter part of pregnancy, the digestive organs may be so affected that it is difficult for the patient to take and retain sufficient food to meet the demands of the body The caloric value of the food should be approximately determined, in order to furnish a basis for the amount given or allowed If a patient be most of the time in bed and reasonably protected from cold, 1,000 kilo calories is sufficient to supply all demands If she be about more or less and use up considerable energy in exercise and heat radiation she will need 1,500 to 2,000 kilo calories Of course, I am not considering cases of slight heart involvement which do not prevent the patient from doing her ordinary work In such cases the needs correspond to those of a healthy pregnant woman The food should contain all the food elements, and preferably in the proportion found in milk Milk is indeed the best food of all if it can be obtained in good condition As the amount required is only from one and one-half to three quarts, the quantity of water which forms a part of the milk is not excessive When it can not be used in whole or part, a menu containing toast, cereals fresh eggs and butter, a few well-selected and carefully cooked vegetables and if borne by the stomach, fresh fruits will answer all requirements All must be prescribed, and nothing left to chance or to the whim of the patient or her friends and attendants So long as the digestive apparatus is in order, the dangers from an improper diet are not recognized A mistake in diet may, however, upset the liver or kidneys and lead to a circulatory disturbance that reacts on the digestive apparatus, and establishes a vicious circle hard to be broken

HYGIENE

The hygienic management embracing regulation of exercise, sleep and rest, dress, bathing, avoidance of infection, etc, should be equally prescribed and controlled by the physician The question of bed exercise in serious cases has been considered already From the principles laid down in the discussion of the prevention of abortion, it is evident that physical exercise must be taken with care Nothing that involves risk of accident should be allowed Exercise should not be too long continued and under no circumstances should the patient become tired This restricts exercise in most cases to moderate walking and to riding over good roads, and proscribes tiring housework, as well as indulgence in active amusements

If the patient is not obliged to remain in bed all the time, she should lie down at least once a day for a half hour or more If the complications are not too disturbing, there is generally no difficulty in procuring a reasonable amount of sleep With the appearance of dyspnea, coughing, etc, want of sleep may become serious and furnish an indication to interrupt pregnancy

Two points should always be made in regard to the dress or clothing of the patient First, there should be no constriction of the body of the patient with corsets or skirtbands The skirts must be light and suspended from the shoulders Second, the underclothing must be warm enough to protect well the skin Skin elimination is not unimportant, and must not be checked

The frequency, kind, temperature and duration of the baths are somewhat important matters, and must be decided on after studying the case Sometimes a cold bath can be borne by one accustomed to it A long hot bath is generally enervating and harmful In the latter part of pregnancy the patient must usually be content with a sponge bath

Of very great importance is the avoidance of infection, and especially infection of the nose, throat and lower air passages The condition of the patient is one of lowered resistance which makes an infection easy A tonsillitis or bronchitis will very quickly change the picture of a smoothly progressing pregnancy to one greatly disturbed, hence all exposure to infection from friends or relatives must be strictly forbidden Pure fresh air is invaluable, but dust from any source—the house or street—should be regarded as poison

The medicines most needed are digitalis and strychnin for the heart, morphin or codein to quiet uterine contractions, and calomel, cascara, salines or other laxatives for the bowels Chloral may occasionally be needed as a hypnotic Oxygen should always be provided in case of dyspnea

INDUCTION OF PREMATURE LABOR

In spite of the best management of pregnancy, the time may arrive when, long before the end of gestation, the condition of the patient is such as to cause grave anxiety and compel a consideration of the advisability of inducing premature labor The indications for the operation are increased frequency of cardiac upsets, palpitation, growing weakness of the heart, as shown by a weakened and more rapid pulse, and increase in edema with disturbed respiration, and a serious impairment of nutrition The operation will be postponed if possible till the thirty-sixth week on account of the child Of course, it may be required earlier, as in all cases of induction of labor the utmost accuracy in determining the length of gestation should be secured All preparations for the care of the infant have been made, the incubator is at hand and the nurse instructed in managing it, oxygen is ready, both for the mother and baby

That method of inducing labor for heart disease should be chosen that is reasonably prompt and certain, and at the same time disturbs the mother the least When there is hydramnion or twins the membranes should be ruptured to furnish at once some relief from the abdominal distension In other cases we would probably choose between the use of the metreurynter and the bougie If the cervix is soft and dilatable and the woman not very sensitive to manipulation, so that one may introduce a small Voorhees bag without an anesthetic, the metreurynter method is to be preferred When the woman is sensitive so that the introduction of the bag would be impossible without an anesthetic or when the cervix is long and hard and not easily dilatable, the bougie method is better As is well known, the chief objection to the use of the bougie is its uncertainty, the duration of labor frequently being thirty-six hours or more In cases of heart disease, however the uterus is more sensitive, spontaneous abortion and labor being common Hence the bougie generally acts more promptly than in other cases For this reason this method may be employed here with a good deal of confidence The details of both these methods are assumed to be familiar to all, and will not be discussed

The essential points in the management of labor complicated with heart disease are careful watching, prompt interference when indicated, the use of ether when necessary, and the free employment of oxygen From the beginning of labor till the completion of the third stage, and in bad cases for hours longer, the physician must be in constant attendance and watch closely the effect of labor on the heart Every preparation for all possible operations must be made Heart tonics and stimulants are administered as needed One of the most important helps is oxygen To one who has never used it in such cases its effects are magical It not only helps the respiration, enabling a patient to lie down who has been obliged to keep the sitting position to breathe, but it also has a soothing effect almost equalling an anesthetic It will, in fact, largely replace ether, which will rarely be needed except in cases of operation

Operative interference may be required in any stage of labor As a rule, there is less danger in the first stage than in the second, and so less indications for interference If the cervix opens slowly and the heart begins to tire, it may be necessary to assist Nature Ether is of course the anesthetic chosen It is safer to give ether than not to give it, for the pain and shock are more injurious than the anesthetic Yet the operation should be as short as possible, hence if it is necessary to dilate the cervix it is better to do so by incision than by manual or bag dilatation, unless the cervix is soft and easily dilatable Dilatation will be followed by rapid delivery of the child either by forceps or by turning and extraction

There is no special rule for managing the third stage Generally the placenta comes away promptly If an operation has been done it may be desirable to remove the placenta at once to avoid further disturbance to the patient Otherwise the cord may be cut short, dry dressing applied, and the patient allowed to remain quiet until the placenta comes away of itself

In accordance with the theories of the causes of the disturbance following the emptying of the uterus, it has been advised to apply sand bags or other weights to the abdomen after the birth of the child to increase the abdominal pressure A good bandage is probably quite as efficient The chief thing to remember is that the danger is not passed with the expulsion of the child, and that then heart stimulants and oxygen are especially needed

The puerperium requires as careful management of the diet, exercise, massage, etc as did the pregnancy During this period, which should include the full puerperal period of three months, the patient may be restored to a fair state of health As a general rule, the mother should not try to nurse the child The outcome depends chiefly on the thoroughness with which the patient follows the plan laid down, even to minute details Here as in hardly any other field of medicine, is made apparent the importance of the qualities of patient persistence in the physician and conscientious obedience in the patient

DISCUSSION

Dr Rudolph W Holmes, Chicago—It is very desirable to have our attention called to heart disease in its obstetric relation, for there is a very popular misconception prevalent as to its frequency and mortality The study of heart disease in pregnancy and labor is based too largely on old statistics compiled at a time when normal and abnormal obstetric cases were inadequately studied The most popularly quoted paper is that of MacDonald published in 1878, but he based his conclusions on only a few severely ill patients, where necessarily the mortality was high, from 50 to 60 per cent, according to the lesion, mitral stenosis being the most serious Recently Fellner made a study of the heart cases occurring in the Klinik Schauta in the past ten years He found first, that 2 4 per cent of pregnant women have heart affections, few only offering symptoms, second, that the mortality was 6 3 per cent, in sharp contrast to older figures—the deaths being largely limited to cases of mitral stenosis A word might well be said regarding morphia in pregnancy It is a moot question if morphia, exhibited in reasonable doses during pregnancy, affects the baby, but there can be no doubt that it may be disastrous to the child if administered within an hour or two before delivery, for then the center of respiration may be paralyzed and the child be unable to breathe at birth The babies of women subjects of heart disease are weaklings and often prematurely born, making the hazard from the morphia all the greater If morphin is to be given it should be a cardinal principle that it may be given in pregnancy to allay uterine irritability The moment labor begins morphia should be given sparingly, and in the second stage should be contraindicated for it offers great danger to the child I have seen babies severely poisoned by the administration of morphia to the mother necessitating protracted artificial respiration The use of heroic doses of morphin in eclampsia, I believe, is responsible for many fetal deaths in that condition In inducing labor I think that there can be no discussion but that the catheter is the most logical instrument for the purpose in this condition If labor is to be accelerated and the os permits it a small flat topped Voorhees bag may be used A large bag ought not to be employed, because there is danger of raising the intrauterine pressure and thereby compromising the heart action If cervical effacement be present I believe the cervical incisions offer a useful means of securing full dilatation and further bleeding is produced which has a beneficial effect on the heart Version or forceps will be employed depending on the conditions. I do not believe, with Fritsch, that the disturbance in the third stage of labor is due to anemia but rather to an overloading of the right heart. Therefore, in the management of the third stage of those heart cases with impaired compensation the indication should be to bleed the woman, if possible. The moment the baby is born and the cord severed, the placenta should be manually removed slowly, so that the cotyledons are torn away gradually, thus enabling one to regulate the amount of blood that is to be lost. It is a distinct advantage to have the woman bleed in order that this congestion of the right heart may be obviated. In conclusion my remarks apply alone to those grave heart cases with a lack of compensation. The labors of women with compensated heart lesions should be conducted practically on the lines approved in normal cases.

DR. N. R. HOTCHKISS, New Haven, Conn.—It has been my misfortune in several cases of mitral disease to have the woman die from cyanosis in spite of all the precautions that were taken. I have the feeling that in mitral disease, where the patient exhibits shortness of breath during pregnancy, we should not permit the case to go on to a natural termination. The earlier labor is induced, the better for the patient. In regard to what Dr. Holmes said of the necessity of blood loss in these cases that go to termination, that is one of the most important things necessary. I have noticed a number of times that the loss of blood relieves these patients very much, and several times I have performed venesection to relieve the cardiac and respiratory dyspnea.

DR. FRANK CAREY, Chicago—While one may agree with Dr. Holmes as to the necessity of loss of blood in a given case, I can not agree with him in the general advocation of going after the placenta at once, and letting that go out as general practice for physicians. There is the possibility of infection and one can not control the amount of blood to be lost by slowly picking off the placenta. To bleed a patient open a vessel and have no difficulty stopping the bleeding. If the placenta can be delivered within a reasonable time, say twenty or thirty minutes, I certainly should not advocate its manual removal, by the general practitioner at least.

DR. HERMAN GRAD, New York—This is an important subject. I know of nothing more formidable to cope with at the time of labor than a bad heart and damaged valves. These cases are exceedingly difficult to manage, especially if they do not present themselves until the ninth month of pregnancy. A case came under my observation recently, in which I found a mitral stenosis. While sitting quietly in a chair the patient was comfortable, but the slightest muscular exertion would send up her pulse and produce cyanosis. When labor began she was cyanosed and unable to lie down. She had to be delivered in the standing posture, with two or three persons holding her erect, and myself kneeling on the floor. It convinced me that if these cases come early in pregnancy, labor should be induced, because the woman is in too great a danger of losing her life. With regard to bleeding, I have observed that the loss of blood relieves these women, and it is astonishing to see how soon afterward they can recline in bed. The patient I mentioned passed through the puerperium in comfort. Six weeks after her confinement she went out walking. On returning home she dropped dead while going up the stairs to her apartment. No autopsy was permitted. She had murmurs all over her chest. Her mother told me that although they knew of her heart trouble they nevertheless permitted her to marry not knowing that pregnancy would be such a serious matter.

DR. CHARLES J. HASTINGS, Toronto, Canada—Some one has suggested the slow peeling off of the placenta to encourage hemorrhage in some cases in order to relieve the engorged right side of the heart. This strikes me as being rather unscientific. While I appreciate the value and importance in extreme cases, of relieving the engorgement of the right side of the heart, yet I think this should be done by venesection, in the usual way. I look on the introduction of the hand into the uterus and the peeling off of the placenta as one of the most formidable and most dangerous operations of labor and should only be resorted to in extreme cases, and always with a gloved hand. In my opinion we have no more valuable drug than morphin at our command, in fact, I think there is no other to compare with it in the relief of cardiac dyspnea and shock. I have never seen any ill results to the child *in utero* follow its use, and I have had occasion to give it in many cases before the birth of the child. I do not question the possibility of its giving trouble, but my experience has not been in that direction. I think we ought to consider well before the induction of premature labor, both for the mother and child. The mental effect on the mother might be more disastrous than the continuance of pregnancy as we often see more disastrous symptoms in the earlier months of pregnancy than later on, providing the patient is carefully watched and treated. Systematic rest, cardiac tonics, careful dieting and proper elimination usually result in satisfactory compensation. We should, therefore, be slow to sacrifice the life of the child. I have had, however, one very grave case where the patient had had two severe attacks of hematemesis as a result of engorgement of the right side of the heart. In this case, in consultation with two of my confrères, we decided to empty the uterus at once.

DR. C. S. BACON—The principal point taken up in the discussion seems to be the management of the third stage of labor, the question of removing the placenta and increasing the hemorrhage. There have been two views held as to the cause of the disturbance after the birth of the child. One, that there is an anemia of the heart, and the other, that there is an engorgement of the heart, two opposite views. It is not necessary to regard either of these conditions as the essential etiologic factor. It is certain that the embarrassment of the circulation continues after the child is expelled. The vascular resistance continues for hours, in fact, for some days. Sometimes death occurs immediately after the birth of the child but more frequently not until some hours afterward. We may assume that the heart is called on to do an increased amount of work, and that this condition is the cause of the fatal termination. These theoretical conditions as to the relative anemia or congestion of the heart need not influence us too much. I doubt very much whether it is necessary to increase the hemorrhage by venesection or by manual removal of the placenta, as mentioned by Dr. Holmes. Remember that the patient is weak, she has been nourished improperly for months, and she has a weak, poorly nourished heart. Why make her condition worse by withdrawing blood? What the patient needs is stimulation before, during and after labor. I wish again to emphasize that the use of oxygen during labor and continued for some hours afterward, is preferable to producing hemorrhage, either by venesection or manual removal of the placenta. The danger of infection referred to by Dr. Carey must be considered, because the patient, on account of her weakened condition and diminished resistance, is more liable to infection at this time than at any other. As to the use of morphin. These children are in a weak condition, and it is probable that this weakness is the result of a disturbed placental circulation and not because of the use of morphin. I have given morphin for weeks and months, in carefully regulated doses, to prevent uterine contractions, and I am convinced that I would have had a spontaneous labor without it. The child was born and, so far as I could see, was not injured in any way. In regard to the nature of the heart lesion. The common belief is that an aortic disturbance is more dangerous than a mitral lesion, but this is not in accordance with Fellner's operations. I do not believe that this is of so much importance as is the condition of the patient. As to the interruption of the pregnancy early. Even though the woman may be in great danger, we have no right to induce labor unless she will consent to it, and I doubt very much whether we have any right to urge the patient to consent. All we can do is to make clear to her the dangers of her condition, and insist that if she wants to go to term in spite of our judgment, that it is dangerous, then she will know exactly where she stands and will assume the responsibility herself. It is wrong to let her go in ignorance of her exact condition.

ORAL INFECTION AND STERILIZATION *

M L RHEIN, MD, DDS
Lecturer on Dental Pathology University of Pennsylvania
NEW YORK CITY

The lack of requisite training of medical undergraduates in dental principles is well understood by our Section Appreciating as we do the bar to general efficiency which this defect in primary education causes, it has been for many years one of the important aims of the Section on Stomatology to endeavor to have proper instruction in dental principles made a part of the medical curriculum To all practitioners laboring under this disqualification, oral infection will always be more or less of a bugaboo This is due to the fact that in order to be able to comprehend any departure from a normal condition of the tissues in the dental region, it is necessary to be thoroughly familiar with the physiologic appearance of these parts

The most important thing in oral infection is, naturally, a proper diagnosis For this purpose it may be best to separate the subject into two subdivisions, first considering it from a standpoint of semeiology, where the local pathogenic condition is merely a symptom of some constitutional disease, and, secondly, from an etiologic standpoint, where the mouth infection may truly be said to be the exciting cause of other functional disturbances

When we consider the vast network of fine capillaries that freely anastomose through the gum tissue, and the fact that they are the arterial terminations of one of the longest of blood courses, it is not unreasonable to suppose that in all forms of malnutrition the tissues nourished by this ultimate capillary network should be the first to exhibit symptoms due to a lack of normal nourishment The gums, the pulps of the teeth and the lining membrane of the roots, by means of which they are properly articulated in the alveolar sockets, are the parts nourished by these capillaries

In all diseases of the vital organs, before any other clinical symptoms are made manifest, these tissues assume a pathologic appearance, varying in character and degree according to the nature and severity of the disease Atrophic changes are liable to be produced by numerous local causes, and thus easily mislead the student When, however, the changes in the local appearance of the gums are merely symptomatic of some constitutional disease, the acute local symptoms continue to increase in severity with the progress of the disease, and in consequence, the clinical aspects of the gums in these vital diseases become great aids in prognosis When the vitality of the local parts is depreciated to a sufficient degree, they become a prey to infection, and the result is seen in the condition commonly known as pyorrhea alveolaris When the stage has been reached where the discharges emanating from the alveolar sockets cause irritation of the surface of the digestive tract, due to the absorption of the toxins by the swallowing of the same it becomes an additional menace to the welfare of the patient

The nature of this discharge varies considerably, due not only to the stage of the disease, but influenced materially by the character of the functional disorder A common error of dentists in speaking of these discharges is to fail to differentiate between those of a mild, almost bland character and those of a more irritating form of sapremia, and from this to a virulent form of purulent effusion

If we are to consider this matter from a scientific standpoint, it is time to cry a halt on speaking of all discharges of this nature as pus, without any bacteriologic evidences of its existence In saying this I do not wish in any manner to belittle the baneful results that frequently ensue from the absorption of toxins where the discharge is nothing more than a simple sapremia Since pyorrhea alveolaris has become a prominent factor, not only in dental but in medical literature, it is not an unusual thing to see erroneous diagnoses of this disease made Dental practitioners frequently confound it with simple alveolar abscesses If this happens it is not unnatural that the medical practitioner should often make serious errors of diagnosis in purulent effusions in the oral cavity

An interesting clinical experience in this respect will better illustrate the point in question

> Miss L, aged about 50, fell down a flight of stairs She was bruised considerably about the face, but paid very little attention to the matter for twenty four hours, when, on account of her suffering, she sent for her family physician, who had been attending her for some time for diabetes
>
> He found the patient showing some temperature, and when, after forty eight hours, this continued to increase so that it ran up to 102 5, and her mouth filled with purulent matter, he sent for a prominent surgeon
>
> After a careful examination the surgeon made a diagnosis of pyorrhea alveolaris, and prescribed a camphor mouth wash The attending physician, accepting the diagnosis made, felt that the patient would receive better attention at the hands of a stomatologist, and I was called in
>
> Instead of finding the patient suffering from pyorrhea alveolaris, there was a comminuted fracture of the alveolar process, extending from the first upper right molar to the left canine, and between forty and fifty pieces of fractured fragments were removed This resulted in the loss of all the teeth in this region On account of the diabetic condition, the delay in proper operative interference left the patient in a very precarious condition Infiltrative absorption had already produced a condition of osteomyelitis, and only the most strenuous efforts of aseptic surgery sufficed to save the life of the patient

In reply to the query of a prominent surgeon as to our methods of diagnosis in oral infections, I said that the same rule applied here that would apply to any other part of the body If there were any possibility of a reasonable doubt, a diagnosis could only be made by exclusion One of the common errors that is made in reference to this pathogenic condition, is the idea that it is confined to middle aged and elderly people There is no age in which a patient can be said to be immune from this disease

TREATMENT OF PYORRHEA ALVEOLARIS

Before proceeding to consider the other types of oral infection, a few words as to the treatment of pyorrhea alveolaris may be of value The original cause of the disorder must be properly diagnosed and brought under proper subjection Where this is possible the prognosis is always more or less favorable if capable local treatment is enforced It is, perhaps, unnecessary for me to state that this means the careful removal of every form of concretion and foreign substance from the teeth and roots and careful polishing of every portion of the teeth and exposed portions of the roots This must be followed up and persisted in at very frequent intervals The important treatment of this condition, however, is preventive treatment It has been demonstrated by

---

* Read at the Fifty fifth Annual Session of the American Medical Association in the Section on Stomatology and approved for publication by the Executive Committee Drs E A Bogue Alice M Steeves and M L Rhein

clinical observation that the frequent cleansing and polishing of the teeth surfaces (done in the proper manner) will so enhance the vitality of the dental region that functional disorders fail to produce the serious pathogenic conditions which result in mouths where this prophylactic treatment has not been used

ETIOLOGY OF ORAL INFECTIONS

We now come to the consideration of oral infections from an etiologic standpoint, that is to say, those cases that primarily arise in the oral cavity and are the original causes of other troubles

First of all, in this respect it may be wise to say that there are forms of pyorrhea alveolaris due entirely to local causes These are most commonly caused by neglect in the care of the teeth and the irritation caused by more or less extensive accretions of the calculi It is also caused by the irritation produced from badly fitted crowns, wedges, injudicious separating of teeth and other causes which too often can be laid directly at the door of the dental attendant Local treatment is a ready cure for all of these cases

Perhaps the most common type of oral infection that is found is the simple alveolar abscess This is caused by the death of the pulp of the tooth which becomes an easy prey to the first migratory bacteria

TREATMENT OF ALVEOLAR ABSCESS

The cure of these cases in the acute stage is a simple matter, and consists in the aseptic removal of every portion of the contents of the root canals, their thorough sterilization and subsequent hermetical sealing

Where the disease has run a chronic course, the alveolar process in the neighborhood of the apex of the root and the outer periphery of the end of the root itself becomes necrosed In such cases it is necessary, in conjunction with the treatment of the root canals, to surgically remove every portion of the necrosed bone and root if a cure is to be effected Extraction of the tooth in itself will effect a cure, and of course is frequently the most efficacious remedy in infirmary practice

At a recent meeting of the First District Dental Society in New York City, a prominent surgeon, reading a paper on this subject, made the remarkable statement that in cases of acute alveolar abscess the tooth should never be extracted until all the acute symptoms had subsided, claiming that it was dangerous to extract in this acute condition He advised the simple lancing of the abscess, allowing the patient to suffer all the effects of purulent absorption, until, as he said, the leucocytes had overcome and defeated the bacteria

It is unnecessary for me to place the ban of condemnation on any such practice before this Section I merely cite it as an illustration of the fact that prominent medical men hold such peculiar views

The main cause for opinions of this kind is due to the fact that physicians are frequently called in to see patients suffering from a more or less severe pyemia, subsequent to the extraction of some tooth They fail to recognize the fact that the pyemic condition has been caused by lack of proper aseptic care of the wound after extraction of the tooth In this way improper dental service is the cause of illogical medical inference Oral infections involving the antrum should receive the same thorough treatment of removal of the focus if a cure is to be effected When infections are absorbed through some of the many channels in the jaws, as per the inferior dental canal, speedy and radical surgical work is required to effect a cure

Whatever the condition may be, a careful differential diagnosis must make clear the nature of the malady

The effect on patients of any of these forms of oral infection is two-fold In the first place, they suffer from the direct absorption of the toxins from the constant swallowing of the contaminated secretions, which tend not only to irritate the digestive tract, but in turn are absorbed into some particular portion of the tract, and frequently serve to increase or start up a chronic autointoxication of the system This, in turn, results in the impairment of some of the functional parts of the body, and it is not an uncommon thing to see an etiologic oral infection causing constitutional derangements which are again manifested most markedly in the mouth by producing the well-known symptoms of pyorrhea alveolaris

NEGLECT OF MOUTH INFECTION

In closing, I wish to call attention to the serious neglect by the general surgeon of the evil effects of mouth infection As stomatologists we realize how small a percentage of people keep their mouths in an aseptic condition The modern operating room is replete with every aid and contrivance that can assist in aseptic surgery Clean aseptic garments are a necessity to every attendant, the mouths of the operator and attendants are covered with sterilized materials, the hands of the operator and assistants are covered with sterilized gloves, the patient is carefully prepared for the operation in every respect, except that of his mouth, which frequently is filled with sapremic, if not with purulent effluvia I leave it to the logical imagination to picture the result of such conditions, especially in intestinal surgery

DISCUSSION

Dr E C Briggs, Boston—I think autointoxication in the alimentary canal plays an important part in the infection of the mouth It has seemed to me, in my examinations of the saliva and of urine in cases of interstitial gingivitis, that I have found the most important indication for treatment to be the thorough cleansing of the alimentary canal One patient may show uric acid diathesis and another only poor nutrition, but in most cases there is a failure on the part of the patient in his daily life to have the alimentary canal thoroughly clean, and as a result he becomes autointoxicated I want to speak of an operation for the correction of prominent sockets of teeth, which I am not aware has been done before It is for the treatment of cases in which the teeth, if left to themselves, erupt and, extending until they have cleared themselves of the gum, project down very far, overlapping the lower incisors and give the "gummy" smile so disfiguring to the patient Sometimes the lower lip almost covers the upper teeth and the smile discloses only the gum Some years ago such a case was brought to me which was very marked This led me to do a thing which I have done in several cases since, that is, the cutting away of the gum and the alveolar process, when it was necessary, to uncover the crown of the teeth in the position I wished them to stand, that is, before they had come down and projected themselves beyond the normal line of the gum After the cutting operation I put in a plate, but later on I found that merely enucleating the tooth seemed sufficient to avert a tendency to project downward I have treated a score of cases in the last six or seven years It seems to me rather a satisfactory operation and I should like to have someone else try it

Dr Stewart L McCurdy, Pittsburg—Dr Rhein's important paper is of special value to the oral surgeon whose work is confined to major operative work Extensive wounds and absorbing surfaces are always present, and one of the most serious complications in operations about the mouth is infection By observing Dr Rhein's points, I think we can secure a more aseptic field and thus guarantee a more prompt repair after operations

Dr A W **Harlan**, New York—Dr Rhein's paper further emphasizes the remarks made by Dr Latham on the incorrect use of terms We have had a paper on pathologic irregularities, dealing with suppurations and displacements of the teeth in their sockets We have had another paper on oral infection which *practically deals with the same subject One gentleman* uses the term pyorrhea in one portion of his subject and in another says interstitial gingivitis To an outsider, knowing nothing about the subject, this would be confusing Interstitial gingivitis is the term that has been coined by Dr Talbot to describe the pathologic changes that take place around the roots of teeth It is an absolutely incorrect term for the reason that many of the lesions of the gums commence, not between the teeth, but on the labial and lingual surfaces of the teeth It is, therefore, improper to use the term interstitial gingivitis to cover the whole field The term which is most used describes the effects rather than the cause, and I must protest against the misuse of terms by men like Dr Talbot, Dr Rhein and others, because none of the terms convey the intended meaning to a non professional person

Dr **Eugene Talbot**, Chicago—I am surprised that such an omniscient man as Dr Harlan should be ignorant of anything I never thought of designating inflammation between the roots of teeth as "interstitial gingivitis," nor does the majority of the dental profession understand it so It shows the greatest ignorance to speak of interstitial gingivitis as an inflammation between the roots of the teeth Every physician and trained dentist knows that interstitial inflammation means sclerotic inflammation of deep seated structures such as is found in the kidney, liver and such organs It never occurred to me when I coined the term that it was absolutely exact, no term can be It means a deep seated inflammation in the alveolar process and not between the teeth any more than any other part of the alveolar process The term is properly understood in this sense by the majority of pathologists If there is one thing on which physician and dentist alike should be better educated, it is infection from the mouth It will not be long before more is definitely settled about diseases of the alimentary canal, especially about autointoxication, intestinal fermentation and appendicitis In some cases I could approximately diagnose appendicitis due to infection from the alveolar process It is a subject which requires the attention of the medical profession and especially of the dental profession

Dr **Alice M Steeves**, Boston—In regard to Dr Harlan's remarks, diphtheria conveys a definite idea to the laity There are many infectious acute diseases of the throat that are named diphtheria by professional people, and while it does convey a definite idea to the laity, always conveys a serious idea and is not always *justifiable* There are many conditions of the throat, such as follicular tonsillitis, etc, not diphtheria Also in typhoid fever there are many conditions of the intestinal inflammations that have in the past been covered up for various reasons, perhaps imperfect diagnosis, under the term typhoid fever As time goes on and these cases are looked into more carefully we know these cases have not all been typhoid fever I think, therefore, that typhoid fever, diphtheria and various other affections are very likely to be used for a number of conditions without conveying any definite idea to the laity

Dr **George F Eames**, Boston—The term interstitial gingivitis has been accepted by many for the want of a better one, but as Dr Talbot has defined it as a deep seated inflammation in the alveolar process, it seems to me that neither the term interstitial nor gingivitis applies to the diseases commonly included in the term pyorrhea alveolaris Undoubtedly numerous diseases of the throat in the past have been classed as diphtheria, at the present time, however, no conscientious physician could make that mistake The microscope settles it beyond a doubt

Dr **Vida A. Latham**, Rogers Park, Chicago—There are no text books that cover properly the field of oral asepsis Dr Hunter's and Dr Marshall's works *are the best* The dentist who meets with all classes of infection of the periodontal tissue—call it pyorrhea alveolaris, if you wish—is at times appalled at the rapid onset and far reaching results We see cellulitis with edema of the cheek so severe that we are alarmed Some people put on cold compresses and advise antisepsis of the mouth, with calomel internally, which is in some cases, perhaps, contraindicated It seems to me that this is a subject which the profession might take up with a great deal of profit, and also make a better study of the growth bacteriologically, following the lines of Miller, Vincentini and Goadby, who have tried to find some culture media on which they can grow the mouth germs This Vincent's angina is sometimes confounded with diphtheritic infections and is a source of danger in a dental office I believe strongly in the fact of auto intoxication, also that these cases of pyorrhea alveolaris or interstitial gingivitis may be caused in many cases by profound anemia, which we know is often due to autointoxication, and these are the cases where we get a neurasthenic type from some maldevelopment through faulty metabolism

Dr. **Rhein**—I had trusted that the purport of this paper would not be misconstrued It was not my intention to make this a subject practically of dental discussion nor to bring in the mooted subject of nomenclature on this point It is well understood by all of us how difficult it is to settle that question, so I referred to the condition as pyorrhea alveolaris, because it is the name by which it is most generally known among the medical men, and this paper is intended for the general medical practitioner Personally, I am ready to adopt the name of interstitial gingivitis instead of pyorrhea alveolaris, if it could be generally adopted I was much interested in Dr Briggs' remarks regarding reimplantation, and I believe that in some cases we may get the results he speaks of I do not believe, however, that we can get better results by reimplantation than with the same amount of surgical efficiency The objection to implantation remains until it becomes disproved that it is only a temporary operation, unless ankylosis should set in, which is present in only a very few cases I will take great pleasure in giving Dr Briggs' method further attention In regard to sterilization, there is not a general medical practitioner, unless he has been especially trained, who would understand what we mean by "placing the mouth in an aseptic condition" That is one of the things that Dr Latham brought out Absolute sterilization of the mouth will always remain an impossibility just as absolute perfection of occlusion will remain an impossibility to the human race What is construed by the medical profession to be placing the mouth in as sterile condition as possible means, as a rule, to brush the patient's teeth and give him a mouth wash A patient who is to be placed on the operating table ought to have every particle of foreign matter removed from the teeth The teeth should be cleansed and polished by a special dental nurse and then the mouth wash properly used will place that mouth in a *comparatively sterile condition so far as the mouth bacteria* are concerned

---

Occupations for Lepers—A Russian physician, H Koppel of Dorpat, of large experience with lepers, attributes their dread of entering an asylum to the lack of remunerative employment in them He comments on the rapid course of the disease at home in comparison with the long survival in asylums, and ascribes it to the lack of medical care of the slight injuries to which their anesthetic condition renders them especially liable At home no attention is paid to these abrasions and they entail long suppuration which undermines the general health He advocates the introduction of various handicrafts for the lepers, making articles that can be adequately sterilized by boiling before distribution outside or any articles for consumption in the asylums, farming, casting, etc, but all with the proviso that the workers are to be paid for what they accomplish He has found it advisable sometimes to hire out the men to neighboring farmers They go directly to the fields and return to the asylum to sleep and eat, and the money they earn is their own They will not work when there is no money incentive, inaction is depressing and the fear of it keeps them away from the asylums where they belong

THE SURGERY OF THE BILIARY TRACT,

ESPECIALLY THE INDICATIONS FOR OPERATION AND THE IMPORTANCE OF DRAINAGE.*

MAURICE H. RICHARDSON, M.D.
BOSTON.

The present communication seems to me justified only in the light of experiences which I have had during the past winter. We are still far from a satisfactory solution of many questions concerning the surgery of the biliary tract. The following are some of these questions:

(*a*) Should gallstones be removed even if they cause no symptoms?

(*b*) What is the importance of biliary drainage after opening the gall bladder or gall ducts?

(*c*) What is the best way of preventing hernia after operations on the biliary passages?

(*d*) What is the significance of the biliary fistula?

From the beginning, hernia in the scar and biliary fistula have been enough to dampen the surgeon's enthusiasm for a procedure which, in many other respects, is one of the most brilliant and effective in modern surgery.

The cause of hernia after operations on the biliary tract is the long incision and the destruction of the motor terminals of the intercostal nerves, and especially the use of drainage, which prevents immediate closure of the wound. The cause of biliary fistula is an obstruction of some kind, usually an overlooked stone, in the course of the common duct. The obstruction may be complete or it may be slight. To some degree, however, it must be present in every case of biliary fistula. Not infrequently the obstruction is the result of chronic inflammatory processes in the immediate vicinity of the common or hepatic ducts.

What more easy and effective way of preventing both hernia and fistula could there be than immediate closure of the gall bladder after the removal of gallstones, or ligation of the cystic duct after cholecystectomy, followed by secure suture of the abdominal wound?

No course of procedure can be more effective than this in preventing these two evils. Instead of hernia and biliary fistula, however, still greater evils may follow.

My own experience has shown that in all lesions of the biliary passages *the most important thing to be accomplished is persistent and prolonged drainage of the gall ducts and the gall bladder.* Furthermore, immediate closure of the gall bladder, cystic and common ducts, after extensive manipulations and perhaps bloody dissections, may be attended by dangers to life of no light weight, and by disasters of the first magnitude during convalescence. Post-operative complications have arisen for which there have been no precedents and to remedy which secondary operations of the utmost difficulty and danger seem to be the last and only resource.

The occasional occurrence of a biliary fistula, for which at the operation no adequate cause could be found, presents a complication not only distressing to the patient, but mortifying to the surgeon. Furthermore it requires an operation sometimes of much greater danger and suffering than the original one.

Three years ago the question of indications for operation in gallstone disease was discussed here before this body. The prevalence of opinion was strongly in favor of the proposition that gallstones should be removed as soon as they begin to offend. Subsequent experience among medical, as well as among surgical men, has, I believe, shown the truth of the proposition. The early removal of gallstones by mechanical art has proved brilliantly successful. This operation would have proved more brilliantly successful, however, had it been possible to make an earlier diagnosis. The weak point of to-day in the treatment of gallstone disease is our failure to recognize it early enough for a simple and uncomplicated operation.

It is not the discussion of diagnosis in these diseases, however, to which I would invite attention in connection with the question of indications for operation. It is rather the discussion of a more radical proposition: "Gallstones should be removed whenever they are known to be present, whether they offend or not, unless the patient's condition forbids operation."

In previous papers I have considered substantially the above proposition, and have advocated exploration of the gall bladder whenever there was a strong suspicion of gallstone disease. The present question differs from the other only in the fact that gallstones are known to be present; it is a question, therefore, which can arise only during the progress of an abdominal operation. It may, of course, be considered, and generally is best considered, after convalescence from the original operation, if that operation is itself a severe one.

Many interesting observations are possible on patients who are known to have gallstones, and especially when the size, shape, number and situation of the stones are known. Without going into details of this sort, however, as beyond the scope of this paper, I would say that many obscure and trivial symptoms may be explained by the known presence of gallstones. Gastric and hepatic symptoms of slight importance, and usually regarded as of no consequence, acquire a significance which is at times remarkable.

Occasionally the gallstones observed at, say, a hysterectomy or some other procedure so formidable as to forbid immediate removal, begin immediately to cause serious trouble. The onset, course and conclusion of the case is watched with extreme interest and, in the beginning, at least, with absolute knowledge of the pathologic condition. At times, I regret to say, the course is observed with keen regret that the stones were not removed at the original operation.

A woman of about 50 submitted in March to an operation for the removal of double ovarian cysts. These cysts were malignant and infiltrating. The incision was a long one, which permitted easy inspection of the gall bladder. The attachments of the gall bladder were long; the fundus was easily delivered; the contents were numerous gallstones, apparently faceted, of similar size and shape, situated in the gall bladder itself; none were impacted and none showed any tendency toward impaction. This was one of a considerable number of similar ones in which I had discovered gallstones in the course of some serious abdominal operation. In some I had removed the stones, and in some I had not. It was obviously absurd to remove gallstones from a patient hopelessly infiltrated with cancer. I therefore let the gall bladder alone. It was palpated, however, by myself and by my assistants.

During convalescence the patient became suddenly jaundiced, but without any very severe pain. The closure of the common duct was immediate and complete The patient, already afflicted by the discomforts of jaundice, soon showed signs of recurring cancer The abdomen became filled with fluid Itching of the skin was intolerable When I saw her last she was in extreme discomfort in every way, and was soon after reported as dying

---

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. DeForest Willard, Charles A. Powers and J. E. Moore.

In another case, at a hysterectomy, I discovered a single large gallstone, completely filling a moderately sized gall bladder The woman, a patient of 45, had been injured in a railroad collision, and presented so many subjective symptoms that it was almost impossible to tell what was real, what imaginary, and what, if any, was feigned She did have some curious subjective signs in the epigastrium, possibly caused by the presence of this stone

In other cases I have followed the histories with some care I am convinced that many patients with gallstones who are regarded as having no symptoms, do in reality have symptoms, and symptoms which are significant or should be significant of some impending trouble

There is one fact that stands out prominently when I review my gall-bladder experiences of the past three years—that fact is the serious pathologic changes sometimes present when the history shows apparently only simple repeated gallstone colics No matter how confident one may be that the patient is passing at intervals small gallstones—without serious objective or subjective signs, without a suspicion of contractions or other abnormalities of the gall bladder and neighboring structures—the surgeon will often be surprised to find instead of a simple, easy removal of gallstones from a slightly affected or apparently normal gall bladder, a thickened, contracted, adherent, infected gall bladder, and an operation of exceeding danger and difficulty This possibility which, with increasing experience, can not fail to depress the surgeon in even the apparently simplest cases, adds a strong argument in favor of removing gallstones which are known not only to exist, but to cause few if any local changes

Local changes of sufficient extent and severity to make operation extremely hazardous are to be considered in connection with other facts in the patient's condition which may contraindicate operation An easy and brief cholecystectomy might be attempted at the close of a severe abdominal operation when a difficult and prolonged operation would be utterly impracticable

The final arguments in favor of removing gallstones, which are known to exist and which cause no symptoms, are First, the known safety of the procedure in the given case, and secondly, the uncertainty of the future in the same case It will be a matter of almost absolute demonstration in that case what the course of operation will be—an easy and successful operation What the course without operation in that case will be no man can tell, except that it may be unfavorable Gallstones never can do good, they may remain at a standstill, and they may suddenly cause irreparable damage Operation may do harm, but in the favorable case assumed, it is almost sure to be effectual in removing permanently a source of great danger and unbearable suffering

It is only when gallstones are discovered in the course of other operations that the conditions influencing the prognosis with and without operation can be accurately determined It is only in this way that gallstones and other conditions of the biliary passages can be said to be or not to be offending The truth of this proposition seems, therefore, more easily demonstrated than that of the former one that gallstones should be removed as soon as they begin to offend The prognosis of operation in the former case is dependent on facts demonstrated only at the operation In the latter the prognosis for operation may be predicted with the greatest certainty possible in surgical cases The prognosis for medical treatment in some instances of real pathologic changes may, too, be reasonably predicted

The second question is that of the essential necessity for biliary drainage after operating on the gall bladder or gall ducts

The advisability of drainage in turn depends on pathologic changes in the biliary tract Are gallstones in themselves evidence of pathologic changes in this tract? Do these changes, whatever they may be, require in all cases drainage as the most important factor for a permanent cure? The proposition here for discussion is "All conditions of the biliary tract justifying the opening of that tract demand, as the most important part of the surgical procedure, temporary drainage of that tract"

The evidence in favor of this proposition is based first on the findings of the pathologist, and secondly, on the experience of the surgeon at the bedside I shall limit myself chiefly to clinical experience Evidence based on laboratory study of individual cases shows for most operative conditions a bacterial cause I have presented in previous papers this evidence in my cases, worked up by Dr William F Whitney and Dr Mark Richardson In some of the cases when least suspected a virulent organism has been found in the biliary tract In some there has been evidence of previous infection of the most serious kind Laboratory research has, in many cases, successfully traced a formidable lesion established through years of slow inflammatory processes In some cases these lesions were in their very inception, in others they were at a stage in which life was seriously threatened In all cases the severity of the condition could either be plainly traced to an infectious source, or it could be predicted as an ultimate result

In a word, the pathologic findings in both mild and severe conditions suggest, if they do not demand, in all cases, both in the slighter ones of beginning inflammations and in the more serious ones of later changes, as thorough cleansing of the biliary reservoir, the ducts and the contiguous structures, as it is possible to give them Such a cleansing is possible only by immediate and long-continued washing out of these tracts by the full, free and persistent escape of bile through the operation wound

From the clinical standpoint, it seems to me, these views are strongly indorsed The operative cases on which my own opinions are based have multiplied in the past three years to such an extent that I feel less uncertainty with regard to drainage than before Briefly stated, the experience is that well-drained cases almost invariably do well Non-drained cases and cases in which drainage is defective, present a considerable percentage of bad end-results When bile begins to flow freely and abundantly through the tube, then for the first time the ultimate result begins to look favorable When bile flows freely through the external wound and also through the intestinal tract, then the ultimate good result seems almost positively assured Not that the result can always be predicted with certainty The anatomy of the biliary tract is so extensive and so far-reaching, the modes and variety of infection and of inflammatory changes is so great, that the combinations of lesions are of great diversity Conditions constantly arise presenting a clinical picture, for which there will be found no precedent. And yet, in the long run, the clinical observer can not but be impressed by the freedom from these trying complications when there has been a biliary drainage with which he has felt perfectly satisfied.

The conditions which I have observed during the past three years dependent on poor drainage or on no drainage, have been roughly divisible into two classes. First, the cases of cholecystectomy, in which I have ligated the cystic duct and closed the abdominal wound, with two or three days' use of a *gauze wick (cigarette drain)*; secondly, the cases of inflamed and contracted gall bladders, in which I have drained the hepatic duct by direct rubber tubing.

These classes comprise the comparatively normal gall bladders, which I have excised without drainage, and the chronically changed ones, in which drainage has been carried on through the remains of the gall bladder. In the former case there was little evidence of long-continued disease; in the latter, abundant. Drainage in the former was evidently less important than drainage in the latter. Indeed, in the latter, drainage was a necessity; it could not have been avoided. The cases include some unusual ones. In one I drained each primary division of the hepatic duct with a separate tube. In some the gall bladder, as well as the common and hepatic ducts, had each a separate tube. In some no tubing could be used, and gauze wicks were substituted. In a certain number of cases drainage began spontaneously after cholecystectomy and ligation of the cystic duct.

As for the lesion, in a few cases there was no gallstone, the symptoms depending on an infection of bile. In some there was no change apparent to the eye. In some the only change apparent was in the color, viscidity, fluidity and other attributes of the bile itself. In some cases it was impossible to tell beyond a question whether all the gallstones had been removed or not. In many cases a single stone had worked enormous damage; in others hundreds had done but little harm.

The diagnosis of gallstones, when made by even the most experienced clinicians, was shown to be occasionally at fault. In prolonged cholemia, especially without pain, cancer of the pancreas was the common lesion found.

The evil results after operation, excluding the fatal cases, all of which have been caused directly or indirectly by the prolonged results of gallstone disease, have been owing to faulty drainage through the abdominal wound; or if not thus caused, they have been coincident with faulty drainage.

The recurrence of gallstones after free drainage with spontaneous cessation of the biliary flow is not worth mentioning. I have seen hardly a case of this kind; in fact, I can not recall a single one. The recurrence of any symptoms whatever after such a course is extremely unusual.

The recurrence of symptoms after the removal of the gall bladder with ligation of the duct is in my experience not uncommon. I recall five cases in the past twelve months. In one, a second operation was fatal. The original operation was cholecystectomy for gallstone cholecystitis. At the second operation—a very difficult one—cancer was found, hopelessly disseminated. In a second case the patient still has occasional chills, with high fever and grave discomforts. The operation was cholecystectomy for gallstones with gall-bladder infection. A third patient presented, after a comparatively normal cholecystectomy, occasional chills and high fever. A fourth, after the removal of the gall bladder or the remains of it and drainage through the cystic duct, has been seized at almost regular intervals with pain, high temperature and jaundice, with occasional bursts of bile and changed fat through the wound. A fifth has similar symptoms after a similar operation.

Careful inquiry among my patients shows a far better collection of end-results after cholecystostomy than after cholecystectomy. I have learned to dread the third and fourth weeks after cholecystectomy, a period when something alarming seems likely to occur, and to expect sooner or later serious secondary symptoms.

From study and experience, therefore, I am led to the conclusion that the essential thing in the surgery of the biliary tract is full free drainage allowed to persist until it ceases spontaneously.

After permanent drainage through the gall bladder the occasions for secondary drainage will be lessened, but if necessary the gall bladder may easily be isolated and drained a second time. After closure without drainage, the necessity for secondary operation will be greater. If the gall bladder has been removed, the secondary operation may be extremely difficult and dangerous, the only channels for drainage remaining being the common or hepatic ducts.

Immediate closure of the gall bladder without drainage is, in my opinion, in itself so hazardous that it is to be condemned.

Hernia in the scar, even after drainage, can best be avoided by using a muscle-splitting operation similar to the McBurney incision in chronic appendicitis. I have used it of late in many cases and like the method. Care may in this way be taken to avoid the motor ends of the intercostal nerves. Sufficient time has not elapsed to show permanent results.

Biliary fistula can be prevented only by leaving an unimpeded flow through the hepatic and common ducts into the duodenum. When a fistula persists the chances favor, first, an undiscovered stone; second, obstruction *from chronic inflammatory processes* in direct contact with the ducts; third, obstructions in the pancreas or at the duodenal papilla.

The existence of a fistula is *prima facie* evidence of obstruction. If long continued, the only relief lies in a second operation for exploration, usually difficult, bloody and unsatisfactory, or in a cholecystenterostomy.

CONCLUSIONS

1. Gallstones should be removed whenever they are known to exist, whether they offend or not, provided the patient's general and local conditions are favorable.

2. Drainage should be employed until the bile spontaneously ceases to flow through the wound.

3. Hernia in the scar is best prevented by a muscle-splitting incision.

4. Biliary fistula means a common duct obstructed usually by a gallstone, and it requires a second operation to close it or a cholecystenterostomy.

NOTE.—The discussion on the papers of Drs. Richardson and MacLaren will follow the paper of Dr. MacLaren next week.

A Law Against the Use of Cocain.—A bill has been introduced in the New York State legislature which goes farther than any other for the prevention of the use of cocain. It forbids the sale of cocain, either at wholesale or retail in any form or in any proprietary preparations, except on the written prescription of a duly registered physician or dentist, and any preparation of cocain or its salts must have a label affixed to the bottle giving the exact contents of the mixture.—*Journal of Inebriety*.

THE UNITED STATES PUBLIC HEALTH AND MARINE-HOSPITAL SERVICE

PART II—THE SERVICE AS IT IS TO DAY

(*Continued from page 604*)

(B) PERSONNEL, PAY AND ALLOWANCE

The officers of the Public Health and Marine-Hospital Service can be divided into three classes—commissioned officers, chiefs of division of hygienic laboratory, and non-commissioned officers The commissioned officers are the surgeon general, assistant surgeons general, surgeons, passed assistant surgeons, and assistant surgeons The non-commissioned officers are acting assistant surgeons, sanitary inspectors, internes and pharmacists

METHOD OF APPOINTMENT

In order to become a commissioned officer of the service it is necessary to pass a competitive examination before a board of officers of the service comprising physical, academic and professional tests, and a general average of 80 per cent is requisite for passing

The chiefs of divisions of the hygienic laboratory are appointed because of proficiency in the work of the division over which they preside, viz, bacteriology, medical zoology chemistry and pharmacology

Acting assistant surgeons and pharmacists are appointed by the Secretary of the Treasury on certification by the Civil Service Commission and recommendation by the surgeon general Internes are appointed by the Secretary of the Treasury on recommendation by the surgeon general and examination by the medical officers of the stations to which they are assigned

The following table indicates the numerical strength of the corps

Surgeon general	1
Assistant surgeons general	6
Surgeons	31
Passsed assistant surgeons	36
Assistant surgeons	50
Chiefs of division of the hygienic laboratory	4
Sanitary inspectors	2
Acting assistant surgeons	195
Medical inspectors	2
Internes	12
Pharmacists (first class, 16, second class, 25, third class, 9)	50

PAY AND ALLOWANCES

The pay of commissioned officers of the Public Health and Marine-Hospital Service is the same as that of officers of similar grades in the Medical Corps of the Army as indicated in the following table

Surgeon general	$5,000
Assistant surgeons general	2,900
Surgeons	2,500
Passed assistant surgeons	2,000
Assistant surgeons	1,600

Officers are allowed furnished quarters, with fuel, lights, etc, or in lieu thereof, commutation at the rates of surgeons, $50 a month, passed assistant surgeons, $40 a month, assistant surgeons, $30 a month When serving outside the limits of the United States, as they existed Jan 1 1898, foreign commutation is allowed at the rates of $90, $85 and $80 a month for the respective grades of surgeons, passed assistant surgeons and assistant surgeons

After five years' service, an additional compensation of 10 per cent on the annual salary for each five years' service is allowed commissioned officers above the rank of assistant surgeon, but the maximum increase can not exceed 40 per cent

When an officer becomes unfit for duty by reason of disability or disease not the result of his own vicious habits, he is placed on "waiting orders," and receives 75 per cent of his salary and longevity pay

Officers when traveling under orders or on special temporary duty receive actual expenses, not exceeding $5 a day

There is no regular salary scale for the non-commissioned officers The various acting assistant surgeons, sanitary inspectors, etc, are paid according to the importance of the posts they occupy and the duties they perform

REQUIREMENTS FOR ADMISSION TO THE SERVICE

Original appointments to the commissioned corps are made to the grade of assistant surgeon, after the applicant has complied with the regulations on admission and satisfied the board of examiners as to his fitness The candidate must be a citizen of the United States, between the ages of 22 and 30, of good moral character, and physically sound In addition to these requirements, he must present a diploma from a reputable medical college, and pass a satisfactory physical, academic and professional examination before a board of commissioned officers of the service

If successful, the applicant is either appointed by the President by, and with the advice and consent of, the Senate, or placed on the waiting list to await such appointment, his eligibility being limited to one year After five years' service, the assistant surgeon is entitled to examination for promotion, and if successful in passing the physical and professional tests prescribed, becomes a passed assistant surgeon

Promotion to the grade of surgeon is made as vacancies in the grade of surgeon occur, and only after due examination

ADVANTAGES TO THE RECENT GRADUATE

This growing service, with its fine record and promising future, is naturally attractive to the young medical graduate Its perfectly equipped laboratory and opportunities for special study, afforded by foreign details, are also attractive to prospective assistant surgeons These manifest advantages should not blind the young man to the fact that there is much hard work, of a routine character, to be done, and that the men doing research work at home or abroad, were so detailed because of special aptitude and as a reward for meritorious and energetic effort in the routine work of the service

The young assistant surgeon is apt to have rather a busy time of it If he is one who desires a lazy existence, he should avoid the Public Health and Marine-Hospital Service, but if he is energetic and ambitious he will find a plenitude of professional work of all kinds, with ample opportunity for research work in preventive medicine

The standard of excellence maintained in the service is not entirely due to the rigid requirements of the entrance examinations The entrance boards, by their conscientious work, are able to select men of promise and high professional attainments, but this is only the first step in the evolution of the trained medical officer from the recent medical graduate

The superiors of a young officer are always medical men, and their fraternal encouragement and sympathy will do much to develop his best qualities He will early acquire executive ability by observation of the systematic business methods and attention to administrative details exacted by his superiors and he will have occasion to exercise this ability and display initiative when placed in command of smaller stations, or when serving on independent details

(To be continued)

FOURTH OF JULY TETANUS

THE EFFECT OF PUBLICITY AND PROPHYLAXIS IN REDUCING THE MORTALITY

One year ago THE JOURNAL[1] compiled statistics of the accidents of the Fourth of July and their results, developing the fact that at least 415 cases of lockjaw had resulted from these injuries It is unfortunate that these figures are the only complete ones ever compiled, for in summing up the cost of this year's celebration the number is relatively so small that we are confronted with the problem of determining whether the occurrence of tetanus as a sequel of Fourth of July accidents was unusually high last year, or unusually low this year Throughout the entire country there has been a general escape from tetanus that seems most remarkable for the total sum, instead of 415, as it was in 1903, is this year but 105 Our figures have been obtained from the same sources as last year and handled in the same way, omitting all doubtful cases, so that the comparison between the two sets of figures is a fair one, the errors in each presumably being proportional

In order that errors may be corrected, we publish, as completely as our information permits, the name and the chief factors in each case, as follows

*Including the time between the receiving of the wound and death

Arranged for comparison with last year, state by state, we can appreciate how general this improvement has been by referring to Table 2

Going over the history of tetanus epidemics as recorded in the statistics of various health departments in several of the larger cities for several years past, we are forced to the conclusion that the apparently very great mortality of last year was not greatly in excess of what it usually has been, taking the country as a whole In some places it was probably unusually frequent, as in Pennsylvania and some cities of Ohio, but in other places, where records of previous years were kept, it was apparent that last year was nothing unusual in this respect For example In 1900 Chicago had 22 deaths from Fourth of July tetanus, while last year there were about 16, and the preceding year 12 New York City, in 1899, had nearly 20, which was, if anything, in excess of last year The tetanus record of 1903 was only apparently large, due to the fact that it was the first time that all the cases in the country were ever collected and published in their enormous total There is every reason to consider, therefore, that the deaths from this cause during the epidemic of this year represent an actual decrease from the ordinary course of events Cities in which previously each Fourth has been followed by from 5 to 10 cases of lockjaw, have this year escaped without a single case Last year Toledo had 8 deaths and this year none, many other cities show a similar escape Chicago had but 5 deaths from tetanus originating in blank-cartridge wounds, which is, with but one exception, the lowest record ever made by that city All over the country the story has been the same The least number of accidents in any year we can remember, and no tetanus"

What is the cause of this splendid improvement? Is it not the result of unusually unfavorable conditions for the tetanus bacillus instead of any cause dependent on other factors? Again, it is to be remembered that it occasionally has happened that for some reason that can not be detected there has been a local escape from Fourth of July tetanus during some years For example, in 1901 there were but 4 deaths in Chicago, and 5 in New York, far below the usual number for each city, and without evident reason May not this year be a similar exception? We have gone over all possible sources of information to decide this point, utilizing reports from hospitals, newspapers, medical journals and correspondence, and the conclusion reached has been against either of these explanations That it is not due to an unusual infrequence of the tetanus bacillus is quite conclusively shown by the fact that during the month of July of this year tetanus from wounds other than those incurred in celebrating the Fourth, has been very frequent, if anything, more so than usual Last year, among the reports received, were 15 of tetanus from simple injuries, this year there were 55, nail wounds, compound fractures and other injuries having frequently had this fatal sequence

The decrease in the disease has also not been local, but spread generally throughout the country Rather, it would seem, the improvement is due to two very essential factors—decrease in the number of wounds received during the celebration of the day, and better care of the wounds that were received

Almost without exception our reports from all places have indicated that the number of wounds was unusually small The statement often received from hospitals has been "This year we had made unusual preparations to care for Fourth of July injuries, on account of the frequence of tetanus last year, but were agreeably disappointed in having almost no cases" The decreased number of injuries seems to depend entirely on the "campaign of education" that has been going on this year as never before Always the daily papers have done a great deal in the way of warning the public of the dangers of Fourth of July celebrations, and urging improvements in its manner of celebrating, but never with such a grand unanimity as this year

When the epidemic of last year was sweeping the country there arose a general demand that such things should be prevented, but it was a repetition of the annual cry, a little increased in force When THE JOURNAL published the summary of the celebrations' cost in life and blood—466 dead and 3,983 injured—a new impulse was given to the receding wave of public indignation

LOCAL ORDINANCES TO PREVENT SALE OF EXPLOSIVES

Fortunately, this did not spend itself in clamorings last autumn, when there was little that could be done because of the remoteness of the next celebration The lesson had been too costly to be easily forgotten One by one events happened to call attention to the need for improvement In this city and in that, new ordinances were adopted to make possible some effective control of the sale of dangerous weapons and explosives The public interest in the topic had become sufficient to warrant correspondents putting accounts of the passing of these new laws on the press wires, and so they aroused attention at frequent intervals throughout the entire country Many medical societies passed resolutions urging the passing of new laws or the enforcement of existing ones, quoting the above figures as impressive evidence of the need of a change, these resolutions were published in the daily press, often accompanied by editorial comment, and in this way the matter was stirred up from another side

Then the press itself took an active interest in the matter, doctors and hospitals were visited, and from them good, sound facts and figures were obtained which were worked up into more or less fanciful "stories" by the versatile reporters We have before us stacks of clippings of articles, published in advance of the Fourth, which make it seem that scarcely a paper in the "tetanus belt" failed to sound an alarm In Chicago some public-spirited citizens attempted to control the celebration of the Fourth entirely, and incorporated an association for that purpose Although it did not receive sufficient financial support to enable it to carry out its large plans, yet it aroused much interest and discussion, and its war cry, "A Sane Fourth," became a by-word With all these factors at work, it is difficult to see how any person who reads the daily papers—and who does not—could have escaped learning that the Fourth is a serious affair, and that blank-cartridge wounds are dangerous sources of lockjaw

EDUCATION OF THE LAITY

The outcome was threefold First, there was the birth of new ordinances in many cities, giving power to the authorities to control the sale of blank cartridges and pistols to minors, or the removal of dust and other incrustations of disuse from the ordinances of other cities where such laws had lain dormant

Secondly, there was made the beginning in the development of a public spirit that was willing to have the laws enforced, so that not a few prosecutions of sellers of firearms to minors were made Thirdly, parents were incited to a more careful supervision of the ways and means of celebration by their children, and even the children themselves often obtained some slight education from their school teachers or parents Consequently, the day passed off with a much smaller number of accidents than had been generally anticipated

In the same way the knowledge of the necessity for very thorough treatment of Fourth of July wounds to prevent the development of tetanus grew among the public, while active campaigning on the part of the medical journals achieved the same results among the physicians For the first time there became something like a general appreciation of the fact that every blank-cartridge or fire-cracker wound is a most likely source of lockjaw This is well reflected in the newspaper clippings A year ago the statement would generally be made that "Eddie Smith shot himself in the hand with a blank-cartridge pistol The wound is not dangerous" This year such statements were seldom seen, but usually they finished with "There is great danger that lockjaw will result" Frequently also would be added "Dr A, who dressed the wound, has sent for some antitoxin, which will be administered as soon as it arrives, in the hope that the onset of lockjaw can be prevented" The sudden change in the situation in one year, as shown by comparing the clippings of last year with those of this July, is indeed remarkable and fortunate, it has probably saved two or three hundred lives

From the reports received it is safe to say that more blank-cartridge wounds were cleaned out under anesthesia, and more doses of antitoxin given prophylactically than after all the Fourth of July celebrations of previous years together Most of the city hospitals and dispensaries that treat large numbers of accident cases equipped themselves with antitoxin before the Fourth and injected it into patients with this class of wounds, in addition to unusually thorough surgical treatment of the wounds themselves

The results were manifest So far as we have been able to learn from a number of sources, not a single patient so treated developed tetanus The most conclusive statement that we have received comes from St Louis It will be noticed that Missouri shows the greatest improvement of any state in the country, practically eliminating Fourth of July tetanus this year, when but one case was reported, as against 29 last year Most of these 29 deaths of a year ago occurred in the two large cities, St Louis and Kansas City, as was the case in all the states, the cities furnishing most of the deaths The following letter explains plainly enough why Missouri escaped

> City of St Louis Health Department,
> St Louis, Mo, Aug 12, 1904
>
> *To the Editor* —Replying to yours of the 10th inst, I have to state the following There were treated in the City Dispensary 36 cases of gunshot wounds, without a single death from tetanus A few days prior to the Fourth of July I issued an order to the city dispensaries to the effect that every case in which there was a possibility of tetanus occurring should be injected with antitetanic serum This order was faithfully carried out, with the result above noted
>
> Last year, out of 56 cases treated there were no less than 16 deaths In a few days I shall be in possession of a report from the chief dispensary physician, and if you so desire I shall be glad to mail you a copy
>
> J H Simon, M D, Health Commissioner

The lesson is plain

An interesting bit of corroboration of the effect of the campaign of education may be brought out by the following fact The reduction in the number of deaths this year occurred in the large cities rather than in the country As near as can be estimated the deaths in the country towns were over half as abundant as last year, while the large cities reduced theirs to zero in many instances, and by 75 to 90 per cent in most of the others The city populace, both lay and medical, is more quickly reached by campaigns of this kind because of the more general circulation of the newspapers, also a large proportion of the city poor with such wounds go to hospitals and dispensaries which are prepared to give them the treatment they need The injured boy in the country is more likely to receive "home treatment," and quite unlikely to obtain surgical treatment

For all of the reasons given above, we must conclude that the reduction in mortality is the result of a decreased number of dangerous wounds, and better care of those that were received, both conditions being due to a more general appreciation by both profession and laity, of their very great danger

DISTRIBUTION

Considering this year's epidemic by itself, and also comparing it with that of last year, we notice that there has been some change in the matter of distribution Pennsylvania leads, as it did last year, with 17 deaths, as compared with 82 a year ago, a decrease of nearly 80 per cent In last year's epidemic 17 cases in one state would have put it in seventh place Illinois passes from third in the list to second, although the actual number of deaths, 15, represents a decrease of 70 per cent from the 49 of last year, this is because Ohio dropped from 67 to 9, an improvement of over 86 per cent, putting it in a tie with New York and New Jersey, Ohio's improvement, like that of Pennsylvania, Missouri and the other states, being due particularly to efforts by the organized forces of the larger cities Last year Missouri and Michigan were tied in fifth place, with 29 deaths each, and although Michigan reduced the deaths by 75 per cent, her 7 is much above Missouri's remarkable reduction to 1 death Four of the states show an increase New Jersey from 8 to 9, California from 2 to 4, Maine from 2 to 4, Utah has 1 death this year, while last year it had none

The number, however, is so small in each that the increase is to be regarded as accidental It is easily possible for such numbers of cases to escape collection entirely one year, and to be collected another year As always, the southern states escape because of a less and a different celebration

AGE OF VICTIMS

Age is, of course, low, yet not a few adults suffered the penalty of playing in the thoughtless manner of youth, while others were injured in accidents that they could not avoid A very few girls also met with accidents of the same kind

NATURE OF THE WOUND

Again, the blank cartridge asserts itself as the cause par excellence of tetanus Of the cases on which information on this point could be obtained, there were 74 from blank cartridges, 18 from cannon fire crackers, 5 from cannons, 1 from bullets, and 1 from a pin-wheel, or 74 per cent from blank cartridges A year ago, however, there were 358 blank-cartridge wounds against 29 from other causes, of which 17 were cannon crackers and 5 cannons

This shows a great reduction in the number of blank-cartridge cases, with the cannon crackers and cannons holding their own It would be interesting to know if this was because particular attention was directed to the dangers of blank cartridges and their wounds as a cause of lockjaw, but no way of ascertaining this is possible As usual, most of the wounds were in the hands, with occasionally one in the leg or other part of the body

DEATHS AND INJURIES ASIDE FROM TETANUS

In connection with the above statements, the facts submitted in Table 3 are of great interest This table summarizes the injuries of all kinds, including tetanus, received in the celebration of the Fourth of July It shows that in addition to the 91 deaths due to tetanus, 92 individuals gave their lives as sacrifices to the national holiday, a total of 183 deaths The casualties from the same cause which did not result in death number 3,986, or 3 less than the figures recorded for 1903 Of these, 349 were of a relatively graver nature, and included 19 cases in which the victim was totally blinded, 61 cases of loss of sight of one eye, 61 cases of loss of leg, arm or hand, and 208 cases in which amputation of one or more fingers was necessitated These figures are slightly in excess of the corresponding items of last year It is noteworthy that the deaths from causes outside of tetanus are increased more than 50 per cent, but no satisfactory cause can be adduced for this increase

Blank cartridges, toy pistols and dynamite canes caused 931 injuries, or nearly 378 less than were recorded from this cause last year Firecrackers caused 1,268 casualties, or 116 more than last year Accidents from careless handling and explosion of cannons and toy cannons caused 508 casualties, or 111 more than in 1903 The number of accidents from gunshot wounds shows a marked increase this year, the respective figures as compared with those of 1903, being 406 and 236, an excess of 170 for the present year Casualties from powder and fireworks numbered 1,056, an increase of 325 over the figures for 1903

We consider that the increase in the number of nonfatal injuries reported does not indicate that more injuries occurred this year than last, but we think that it is due to the fact that more attention was paid to the subject this year, owing to the agitation of the subject through the efforts of The Journal, in which nearly every newspaper in the country assisted This interpretation of the figures shown does not apply, however, to the 50 per cent increase in the number of deaths from causes aside from tetanus for such a death is pretty sure to be chronicled

A detailed list has been compiled of the 4,449 persons dead or injured, giving the name or description of each, the nature of the injury and the cause These are classified under cities and states, and from this list Table 4 has been prepared Only such cases have been listed as presented names and data, or, in the absence of the name, a case has been included when it bore such marks of identification that it could be distinguished from other cases in the same city All doubtful cases have been omitted, as well as injuries from runaways, fright, fires or other indirect injuries even though the cause of the accident was a firecracker or other explosive

The first column of *causes*, that of blank cartridges, includes blank cartridges and toy pistols, also a large proportion of injuries from the use of the cartridge cane

DURATION AND PROGNOSIS OF TETANUS

As is usual with children, the period of incubation and the duration of the disease are usually short, although in the series for this year the time seems to be somewhat longer than last year, which may be more apparent than real, and due, perhaps, to the greater number of adult victims A very early onset and a rapid course is frequent in these cases The prognosis seems to have been bad, fully as bad as last year In a number of the cases of our series we were merely informed that the patients had developed tetanus, but for one reason and another did not succeed in learning the final outcome All such cases we have left blank in the "result" column Of definite recoveries we have information concerning but four, while two others were reported as "recovering"

This corresponds closely with the record of last year, when we learned of 7 actual recoveries among 415 cases, and shows only too conclusively the hopeless nature of Fourth of July tetanus, once it has developed We have also very positive evidence that it is much more fatal than tetanus from other wounds, for during the same period of time we learned of 55 cases produced by ordinary accidents, such as nail wounds compound fractures, etc, of which 10 recovered, and in 8 the result was not learned, making the mortality approximately 80 per cent

The reasons for this greater mortality in Fourth of July tetanus are probably two-fold First, the average age of the patients is somewhat younger yet not so much so as might be imagined, for a very large proportion of the every-day cases is furnished by the barefooted boy who steps on nails, glass and slivers

Second and perhaps most important, is the nature of the wound As we have pointed out in other articles the great amount of tissue laceration, necrosis and hemorrhage furnishes ideal conditions for the multiplication of the tetanus bacillus with a correspondingly large quantity of toxin produced and absorbed It would seem that no great improvement in the treatment of tetanus has been made, but this matter we will discuss later under the heading of treatment

THE CAUSE OF FOURTH OF JULY TETANUS

In our article of a year ago we discussed very thoroughly the question of the origin of the infecting bacilli, because there had been a great deal of controversy as to whether the bacilli were contained in the cartridges themselves After considering the evidence available for each side of the question, we came to the conclusion that there was no convincing evidence that blank cartridges contain tetanus bacilli, except possibly as a rare contamination when they have been exposed to dirt On the other hand, there was abundant evidence that they were present in the street dirt and on the persons and clothing of the injured people The most reasonable assumption at that time was, therefore, that the organisms are carried into the wounds from the surface at the time of the accident Since that time there have been no developments calling for any modification of this view

Occasionally brief notices have appeared that this or that person has found tetanus bacilli in blank cartridges, but so far as we have been able to learn no definte reports of such findings have found their way into medical literature While there is no particular reason why tetanus bacilli may not be found in blank cartridges, still there is no particular reason why they should be there. The raw materials of which the cartridges are made are not such as to render them likely occupants of the cartridge, and the method of manufacture is such as to make their destruction almost certain

The popular idea of the presence of dirt in the powder or dirty straw in the wads seems unfounded. It is on record that 759 cartridges, representing all makes, have been examined by Wells, Taylor, La Garde and the Boston City Health Department, all with negative results The incomplete reports of positive findings may be due to the occurrence of the forms of pseudo-tetanus bacilli, described by Bain and by Wells, which, without animal experiments, might readily be mistaken for the pathogenic form, although they themselves are harmless saprophytes

The great danger of blank-cartridge wounds seems to lie not in the presence of the specific organisms in the cartridges, but rather in the favorable nature of the wound As we have explained more fully in previous articles, their form and location favors ideally the development of these anaerobic organisms, and they are received at a time of year when tetanus is most abundant and by persons who are particularly well supplied with the germ-ladened street dirt.

That this year 26 per cent of the cases came from wounds made by giant crackers, cannons and bullets, would seem to indicate that the blank cartridge has no monopoly on the bacillus if it is contained in the explosive, as some have maintained The only thing these different explosives possess in common is the powder, yet we do not hear of tetanus following the very abundant accidents in which hands and faces are burned with powder and often blown full of the grains And also, it should be remembered that 55 cases of tetanus produced by simple injuries were brought to our attention during the month of July All these considerations make it seem more probable than ever that in most, if not in all instances, the infecting bacilli come from the dirt carried into the wound, and not from the explosive itself

PREVENTION AND TREATMENT

The history of the past two years shows plainly that something can be done in the way of prevention and also that a good start has been made in the right direction It now remains to be seen if progress will continue Unquestionably, the proper point of attack would be the prevention of the wounds which cause the disease, and this can be achieved only by preventing the use of pistols, cannon crackers and cannons Had this been done this year there would have been but one death from lockjaw as a result of the celebration Enough was done, however, to certify to the feasibility of the enforcement of laws in this direction

The enforcement of laws, however, rests always on the state of public sentiment, and no better illustration could be offered than the experience of the city of Toledo Last year Toledo suffered in proportion to population more than any other city in the United States, losing 8 lives from lockjaw, besides having many other injuries This year Toledo not only escaped loss of life, but also suffered no accidents whatever, and the dependence of this on the state of public sentiment is conclusively shown by the following letter

> Department of Health, City of Toledo, O, Aug 6, 1904
>
> *To the Editor* —Your letter of the 5th inst in regard to Fourth of July mortality at hand and contents noted
>
> It is a great pleasure to me to report that there was not a single fatality of any kind following our Fourth of July celebration, nor were there reported to us any injuries which did not prove fatal
>
> Indirectly, this condition of affairs resulted from an ordinance passed by the City Council regulating explosives, though it must at the same time be borne in mind that our late mayor, Hon Samuel M Jones, was on his death bed, and, as he had expressly wished for a quiet Fourth, and had been the leading spirit in the passage of this ordinance, the love that the people of the city bore him caused them to be unusually careful
>
> W W Brand, Health Officer

The improvement in the cities as compared with the country may, in part, be due to the possibility of police regulation of the sale of dangerous explosives, and just as the laws were enforced so the city escaped or suffered For example Chicago enjoyed a great decrease in mortality, but still lost five lives from blank-cartridge wounds, corresponding to a much-improved but still somewhat defective control of this sale This is shown by the investigation by one of the daily papers, which has always taken an active interest in this subject, reported as follows

> An investigation made yesterday by the *Tribune*, with the aid of a 14-year old boy who did not appear to be more than 11 years of age, showed that the law generally was ignored Within a few hours this boy purchased in small stores located in different sections of the city three cartridge toy pistols, one paper cap toy pistol, fifteen cannon crackers of various sizes, and three explosives which the woman shopkeeper said she thought were "cannon crackers," although she did not know just what they were
>
> In each of the stores where the boy purchased the toy pistols cannon crackers also were on sale At a number of places visited he was refused pistols or cannon crackers on the ground that the Fourth of July does not come until Monday, or because they "had sold one and got into trouble over it" At several stores he was denied cannon crackers but was offered sky rockets and other fireworks, the sale of which is forbidden by section 676 of the municipal code of 1897 although this section of the ordinance is not enforced during the Fourth of July season
>
> The territory covered included only a portion of the south side, and the north side to North avenue In only one north side store was the boy able to buy either a toy pistol or a cannon cracker He secured a paper cap pistol at Bachrach's, in North Clark street All of the other dealers in this section either declared they had no cannon crackers or toy pistols, or that they were not allowed to sell them to minors

Compared with our experience of a year ago, this shows a decided improvement, although still far from the right state of affairs It seems to have been about the same in most of the other cities

What is now to be dreaded is that even the partial correction of this crime of selling pistols and giant crackers to children that has been accomplished this year may not be continued next year There is no question that the manufacturers stand ready to supply and to push the sale of these death-dealing toys, regardless of consequences, and unless the agitation continues, the candy and notion store will supply the materials for self-destruction as before Undoubtedly, the proper place in which to check the trouble is in the manufactories themselves Not until there exists laws prohibiting the manufacture and importation of toy pistols, blank cartridges, giant crackers, and any other equally fiendish instrument of disorder that can be devised to take their place, shall we be free from a greater or less annual epidemic

Vigorous efforts on the part of the authorities of each community can decrease the severity of the epidemic, but so long as these things are obtainable small boys will die of lockjaw It is in such matters as this that a medical representative in the higher branches of government could accomplish much for preventive medicine We would repeat the suggestion that the Association take up this matter at its next meeting, and attempt to arrive at a means for securing legislation directed toward the prevention of manufacture or sale of these articles As they have no use whatever outside of purposes of celebration there can be no logical reason for insisting on their production, except the demands of commercial enterprise

The children will have plenty of means left for celebration in the way of torpedoes, small fire crackers, pistols shooting the harmless paper caps, and display fireworks The chief nerve-rackers of the day would be gone, and the substitution of a "sane Fourth" might become a possibility, using methods of celebration of our real national holiday better adapted to inculcate patriotism than are those now in use, which smack more of red anarchy with its bombs and pistols

In the meantime, let us as a profession encourage and aid in all ways the efforts of the daily press to educate the public to the dangers of present conditions that the progress made this year may be continuous

Antitoxin —The prophylactic treatment of all blank-cartridge, giant-cracker and other similar wounds of the Fourth has been demonstrated to be positively successful many times before, but probably never on so large a scale as this year Not only was thorough cleansing of the wound by vigorous operative measures enforced with great success and frequently, but prophylactic injection of antitoxin was employed in more cases than ever before In many large cities the hospitals and dispensaries were provided with antitoxin before the Fourth and used it on all cases of injuries of this character, and not a few private practitioners used it in cases coming into their care We have now records of upwards of a thousand administrations of antitoxin in this way without a single untoward result of any importance, and without a single case of tetanus developing What motive can there be, therefore, in treating a Fourth of July injury without the prophylactic injection? The cost can not be a consideration when the danger is considered on the one hand, and the abundant sources of charity for those actually unable to afford it on the other Let us repeat the figures of the St Louis health commissioner Last year, of 56 blank-cartridge wounds treated by ordinary means, there were 16 deaths from lockjaw This year 36 similar wounds were treated with antitoxin injections without a single death What could be more conclusive than that? And also, in the Harlem Hospital, there were treated 100 pistol wounds without a single case of tetanus following, antitoxin being used freely[2]

But what is to be said of physicians who saw blank-cartridge wounds this year, washed off the surface, applied a dressing, and told the parents that there was no danger? There were several, how many we can not know, but a good many of the 105 who died from tetanus owe it to the "care" of such men as these If at this time there is a man practicing medicine who does not know how to treat a blank-cartridge wound, what is he fit to treat?

We can add nothing to the suggestions made before the Fourth[3] Thorough exploration of the wounds, removal of every particle of foreign matter and necrotic tissue, and free drainage from the bottom is the only rational and safe procedure, followed as soon as possible by an injection of 5 to 10 c c of tetanus antitoxin It has been suggested that dry powdered antitoxin be sprinkled over the wounded surfaces, but the operation of injection is such a simple one and so much more certain that it seems to us far better, particularly as we have learned of one case of the use of the antitoxin powder that was followed by tetanus As this method of treatment is so absolutely efficacious the 105 deaths from tetanus mean just so many instances of criminal neglect or carelessness on the part of some one, usually, but not always, the patient or his parents

We can not boast of the results of the treatment of these cases, with a mortality between 95 and 98 per cent, but so far as we have learned, in but a few were any of the more advanced methods, described in the article referred to, given a fair trial Many of the patients first received medical treatment less than twenty-four hours before their death, being in the last agonies of acute tetanus Most of the others were treated in the usual way, with sedatives and subcutaneous use of antitoxin In view of the ineffectiveness of this method, it is well to discard it for anything that promises better, and according to the results so far obtained, the most hopeful method consists in the injection of the antitoxin into the spinal canal, preceded by withdrawal of as much as possible of the toxic cerebrospinal fluid, and accompanied by injection of antitoxin into the large nerve trunks leading from the injured part The details of this treatment will be found in our article of June 18, 1904

Injection of Salt Solution—The salt solution advocated by Mathews, which depends largely on the effect of the calcium it contains in lessening muscle irritability, has been used, to our knowledge, in one case of blank-cartridge tetanus A marked lessening of the rigidity was observed and the force of the contractions greatly lessened, so that the boy seemed in a fair way to recover from the tetanus, but unfortunately he developed an aspiration pneumonia and died on the fifth day, so that the final result of the injections can not be determined One case of tetanus following a barbed-wire injury treated in this way in Iowa during July has recovered As the solution does not interfere with the administration of antitoxin in the ways recommended the salt solution may be used as an adjuvant until we can learn something of its value

The same may be said of Murphy's suggestion, the use of eucain and morphin in intraspinal injections, reported by him in THE JOURNAL, Aug 13, 1904 In fact, it is perfectly possible to combine the various methods of treatment most generally used, and thus give the patient the benefit of their several possibilities, only care must always be taken not to disturb him too much

TRAVEL NOTES

VII *

A WINTER SEMESTER

LEWELLYS F BARKER, M D

CHICAGO

MUNICH, July 21, 1904

For a certain period the globe trotting method of travel may please and satisfy, but after a time it palls When picture galleries have been seen by the dozen, palaces by the score, and churches by the hundred, the esthetic sense becomes over saturated and refuses to take up more The alimentary tract, too, rebels against the bustle of the railway station and the continuance of life in "grand hotels" The centers of benevolence gradually undergo cloudy swelling, hypertrophy with tendency to degeneration, through enforced over activity in the matter of *la buonamano* Desultory visiting of hospitals and physicians, easily stimulating for a time, meets with an ever rising threshold as the weeks pass The body craves a more regular life and the mind demands greater intensity and less diversity of occupation It is, therefore, with a feeling of relief that, entering Germany from Italy, the physician finds in Munich a city eminently suited to a medical stay of months rather than of weeks or days, a city which while offering unusual opportunity for the quiet enjoyment of life, also presents exceptional facilities for more concentrated medical work

MUNICH

The *Münchener*, celebrated for his *Gemüthlichkeit*, gives the visiting stranger a warm welcome, points with pride to his university, directs him to the Pinakotheks and Glyptothek, tells him of the theaters, of the opera and of the concerts in the Kaim Saal, recommends his favorite brew of beer, and offers to meet him at the Café Luitpold, the Rathskeller, or the Künstlerhaus

No better place could be chosen for an overworked nervous American to recuperate in The air, as is well known to German neurologists, is especially beneficial to the neurasthenic, and the Bavarian motto *Der Mensch ist kein Eilwagen* is more easily lived up to in Munich than in most places

In the southeastern part of the city, between the *Sendlinger Thor* and the *Theresienwiese*, you find the general hospital, the various clinics, and the scientific institutes of the medical faculty A strong group of men is at work there The venerable Karl v Voit is at the head of the physiologic laboratory, ably supported by Max Cremer and Otto Frank Since v Kupffer's death Johannes Rückert has been professor of anatomy, descriptive and topographic, and Siegfried Mollier is also professor of anatomy, histology and embryology The distinguished Otto Bollinger is professor of general pathology and pathologic anatomy, with Hans Schmaus and Hermann Dürck as members of his staff After Buchner's death Max Gruber (of the Gruber Widal reaction) was called from Vienna to succeed him as professor of hygiene and bacteriology, Martin Hahn is extraordinary professor in the same laboratory, and Dr. Tromsdorff is assistant. R. Emmerich is also a professor of hygiene, and v. Tappeiner has pharmacology. On the clinical side Munich is fortunate in having as professor of internal medicine a man regarded by many with whom I have talked as the foremost clinician in Germany, namely, Friedrich Müller. Formerly von Ziemssen had had the medical clinic and von Bauer the propadeutic. When von Ziemssen died the chair of medicine and the medical clinic were divided between v. Bauer and Müller. Surgery is headed by von Angerer, a genial man, much beloved by his patients, a favorite in court circles and known as a good shot in the hunting field. v. Winckel is the gynecologist and Eversbusch the ophthalmologist. In psychiatry Munich has been lucky enough to secure the best man in the country in the person of Emil Kraepelin. When his new psychiatric institute, now building, is completed, the opportunities for the scientific study of psychiatry in Munich will probably be unparalleled. As my time in Munich was given over almost entirely to Friedrich Müller's clinic and the State Chemical Laboratory, I am better able to write of the work in internal medicine there than of the work in the other medical branches.

[2] Correspondence from Dr W H Luckett.

[3] Prophylaxis and Treatment of Fourth of July Tetanus THE JOURNAL A M A, June 18 1904, p 1621

*The previous articles in this series have been as follows 'Travel as a Means of Post Graduate Medical Education," by Dr Nicholas Senn July 23 Is a Trip to Europe Worth Its Cost to the Medical Man? by Dr Lewellys F Barker July 30 Spain and Ramon y Cajal, by Dr Barker Aug 6 Leprosy in the Hawaiian Islands,' by Dr Senn, Aug 13 Italy and the Great Antimalarial Campaign by Dr Barker Aug 20 and 27 Father Damien the Leper Hero by Dr Senn Aug 27

One drawback to the medical clinic in the Bavarian capital is the lack of a real university hospital. The internists are compelled to use the General City Hospital with all the hindrances to scientific work which such an arrangement entails. It is a great pity that a large city like Munich, with so able a faculty, has not its own university hospital, where selected cases could be studied and treated. But the university has formed a close alliance with the city hospital, and von Ziemssen was able to secure a special university building built in juxtaposition to it, known as the Medical Clinical Institute, fitted with teaching laboratories, lecture amphitheaters and research rooms.

The amount of clinical material available for study and teaching is not great; it does not compare in amount or variety to the clinical material of Berlin, Vienna, London or Paris. It could, however, be increased, and doubtless through Friedrich Müller's influence will be. Moreover, it is just possible that the material is better worked up as it is than if it were accessible in greater quantity and diversity.

When Müller accepted the call to Munich a new arrangement was made. Instead of "Medical Clinic" and "Propadeutic Clinic," the Institute and work were divided into two equal and co-ordinate parts, the First and Second Medical Clinics. Each clinic is independent of the other. Students may attend either of the clinics or both, but must be examined by two or three professors—Müller, v. Bauer and May (the latter is at the Poliklinic). Each half of the Institute has its own separate and distinct lecture room and laboratories, and each professor has his own wards in the General Hospital. The teaching laboratories are in one part of the clinical building while the laboratories for strictly scientific work are in another, more secluded part. There is a library of internal medicine used in common by the two clinics. In the teaching laboratories opportunity is afforded for instruction in clinical microscopy, clinical bacteriology and clinical chemistry. The more strictly research laboratories are excellently designed for investigation in chemistry, bacteriology, physiology and pathology. It is admirable to see the effort made to bring these sciences directly to bear on the clinical cases. While much can be done, as has been demonstrated in America, by a harmonious working together of the clinic on the one hand, with the laboratories of pathology, physiology, bacteriology and chemistry proper on the other, still scientific work must surely make more rapid progress when special laboratories for the direct application of the methods of these sciences, manned by skilled workmen, are installed in the clinic itself. Some excellent research is going on in the laboratories under Müller's direction, especially along the chemical lines in which he is so deeply interested.

Just here I may be permitted, perhaps, to digress in order to make a few general remarks concerning the difficulties which so far as I know confront would-be workers in clinical laboratories in all countries, difficulties which for the most part are due to the lack of proper laboratory organization. The clinical laboratory is everywhere, as yet, an unformed creature, a more or less chaotic appendage, subsidiary in interest and in regulation to the work of the wards. This is largely due to insufficient staff, insufficient funds, and, except in a few clinical laboratories, to insufficient interest in the clinical laboratory work on the part of the higher clinical men. Not until the clinical laboratory adopts the methods of organization so admirably worked out in the laboratories of pure chemistry can its work be expected to become very effective. In laboratory work it does not do to have the apparatus as common property. It should be possible in a clinical laboratory as in a chemical laboratory to secure reagents and glass when they are needed. There should be a storeroom under lock and key, in care of a storekeeper, open at regular hours where stores can be drawn on by personal written requisition. There should be adequate janitor service. Each worker should have his independent working place, his own outfit, which he can lock up in his own cupboard, his specific routine, his particular problems. Where a certain amount of money is available, all this, with proper organization, can run as smoothly as clockwork. But without intelligent organization everything is agog. Everybody's property is nobody's. To secure a burette for yourself you must waste a co-worker's normal solution. The newcomer seeking a funnel holder for himself and finding one on your desk, runs the risk of spoiling some valuable quantitative estimation you are making. With the storeroom unlocked the phenylhydrazin is never in its place, the hardened filters disappear into one worker's locker, the glass beakers vanish, and graduated cylinders become a rarity. In the absence of a storekeeper and the requisition system, responsibility can seldom be fixed, the whereabouts of apparatus are enigmas, stores are exhausted and no new supply ordered, excess and waste go uncontrolled and experiments have to be conducted faultily if at all. Research is ever discouraging enough without the aggravated evil of an unorganized laboratory.

If we are to hope for fruitful investigation in our clinical laboratories we must see to it that those who work in them have proper facilities and conveniences, that order and system prevail, that proper encouragement and adequate supervision are provided. I make this digression here because I believe that the Munich laboratory under Friedrich Müller's direction is likely to become one of the best organized clinical laboratories in Germany. Interested in laboratory work as Müller is, a highly productive laboratory worker himself attracting ambitious young physicians from all lands to work with him, familiar with the methods and arrangements of German chemical laboratories and endowed with unusual executive ability and organizing power, it would seem as though it were to the clinical laboratory in Munich that we might look if anywhere in the near future for a proper development and a systematic organization.

The routine work of the medical clinic in Munich, even with a relatively large staff of older and younger assistants, makes heavy demands on the time and energies of the director. From 9 to 10 each morning (Saturday included) there is the medical clinic in the amphitheater; from 10 to 11 a percussion and auscultation course is given by Müller himself; from 11 to 12 he holds examinations and is occupied with ward visits. Between 12 and 1 o'clock the research workers in the laboratories are visited and advised. Consultation hours are from 2 to 4 p. m., and the hours from 4 to 6 are devoted to clinical and laboratory work. The evening is given over to medical reading, medical writing and the preparation of the lecture for the clinic the next morning.

Friedrich Müller was a pupil of Gerhardt's, was for several years the assistant of that great physician, and is thoroughly imbued with the clinical investigative spirit of his former master. How much he reverenced Gerhardt is evident from the necrologic notice he wrote of him in 1902; how much he has been influenced by him can easily be discerned by visiting his clinics and making his personal acquaintance His 9 o'clock clinic is largely attended by the *Praktikanden* in Munich, the seats of the clinical amphitheater are all occupied and often a number of men are compelled to stand And that this popularity is well deserved and does not depend on any catering to the lower motives, one can convince himself by regular attendance for a time There is nothing of the *grosses Thier* to be detected Müller's assistants attend the clinic to help him with experiments and demonstrations and to learn from what he says, but for no other reason No effort is made to mollify or amuse students, earnest, exact, honest clinical work and carefully prepared lectures are the only inducements held out Strict with himself, Müller is strict with his assistants, with nurses, and with students, the order, discipline and punctuality that result can scarcely fail to excite the sympathy and approval of the visiting onlooker

As I have said, the clinical material in Munich is not so abundant as might be desired There are no free beds in the American sense, many of the patients are paid for by the societies for invalid insurance The German arrangement known as the *Krankencasse* sends to private physicians great numbers of patients who should be hospital patients Besides, the medical profession as a whole in Munich has not yet learned to co operate with the university clinic Later, when practicing physicians feel more keenly than they do at present their duties toward the medical education of the coming generation of physicians, they will, when they in their private practice meet with particularly interesting cases which are suitable for demonstration, bring them to the director of the clinic for presentation to his class Individual physicians of the better sort have already made a beginning in this direction, and as soon as the Munich doctors realize how fairly they are treated under such circumstances and how helpful they can be in this way, the practice will doubtless grow

Müller's clinical lectures are models of clearness, terseness and force It is not always easy for the clinician, whose audience consists of clinical beginners on the one hand and more advanced students and postgraduate workers on the other, to so plan his address and the presentation of his case that all his hearers shall be interested and instructed Two or three students are always called to the side of the patien the Socratic method of teaching is often resorted to though not to the exclusion of the clinical lecture proper I was astonished at the simplicity of Müller's talks, and it occurred to me that perhaps in America we sometimes assume that our students know more than they do, that we sometimes overestimate their preparedness and assimilative power and in consequence fire over their heads Müller makes relatively few references to the bibliography of his subject, uses plain language, avoids unusual technical expressions, assumes a fair knowledge of anatomy, physiology and physiologic chemistry but does not presuppose extensive clinical knowledge or experience (beginners in clinical work can not possibly have them) The student is led from the anatomic and physiologic knowledge he has, through the anamnesis and the exact observation and examination of the patient, gradually up to the point where the diagnosis "makes itself" As a teacher the Munich professor has learned that very important lesson of beginning at the beginning, he does not, for example, inaugurate the clinical study of tabes with a minute description of pathologic changes in the spinal ganglion cell It is the "complaint" of the patient that is first listened to and this forms as it should always do, the starting point and, to a certain extent determines the course of the whole clinical investigation The complaint of the patient, it may be urged, is sometimes very misleading, true, but harm never results from taking it as the commencement of the clinical study, provided the patient is subsequently questioned in all directions and the whole body is examined thoroughly by all the methods at the clinician's disposal The beginner learns from observation in the clinic the great significance of the anamnesis in some cases and in others the fallacies to which it may lead Above all he comes to realize the importance in every case no matter what the anamnesis, of the thorough objective examination extended to all the organs and regions of the body

Müller demonstrates as much as possible, even when it is necessary to cut the clinical lecture short to do so, attention is called to the visible symptoms, the recognition of the physical signs is compelled The chemical tests of urine, feces and sputum are made at the time (not simply reported to the class) The bacteriologic and cytologic slides are under microscopes at the table where all may examine them When antitoxin is administered the serum is shown, when oxygen gas is advised in treatment the oxygen balloon is exhibited and its method of use illustrated I have even seen an ordinary hypodermic syringe passed around the class! Illuminated *x* ray photographs are shown, blood pressure readings are made, gross specimens from the autopsies are presented microscopic sections from diseased organs are projected on the screen In short, the method of object teaching or the principle of *Anschaulichkeit* is followed *ad maximum*

Clinical Report

A CASE OF TETANUS TREATED SUCCESSFULLY WITH ANTITETANIC SERUM

T G ODELL, M D

AND

C C SNYDER, M D

SALT LAKE CITY

Patient—S B, aged 17, occupation, porter in wine cellar Family history negative He was admitted to the Holy Cross Hospital July 22, 1904, suffering from a well defined case of tetanus The following history was obtained after the patient had recovered sufficiently to talk

History—On July 4, while setting off a fire cracker the palm of the left hand was injured This did not cause much trouble until July 11, when he complained of some pain and stiffness in the muscles of the neck and back These symptoms were not severe, but had increased somewhat by July 15, when a physician was called and diagnosed the case as "muscular rheumatism," and ordered antirheumatic treatment which was continued until July 22 The patient was confined to bed

Examination—At this time our attention was called to the case, and on examination we found the following symptoms present Risus sardonicus very marked, tonic spasms every two minutes, opisthotonos exaggerated by the slightest noise or excitement, jaw locked to the extent that it would not admit a lead pencil between the teeth, temperature 104 F, pulse 120, constipation, no difficulty in swallowing and no pain

Treatment and Result—Patient was sent to the hospital when we had finished the examination, and at 8 p m 20 c c of anti tetanic serum were administered subcutaneously This dose was repeated at 12 o'clock midnight, and a similar dose given every eight hours until 220 c c had been used He was also given morphin sulphate, gr ¼ and atropin sulphate gr 1/100, hypodermically

No improvement was noticed for 36 hours, when the jaws relaxed sufficiently to admit an ordinary lead pencil between the teeth There was a very slight improvement in the spasms temperature 102, pulse 110 At this time chloral hydrate in 15 gr doses was given by mouth every four hours

July 25 there was decided improvement, the jaws relaxed three quarters of an inch, chloral and serum were discontinued and sodium bromid in 15 gr doses was given every four hours temperature 99, pulse 100

July 26, jaws relaxed one inch, patient was able to chew continued to improve, and was discharged from the hospital cured Aug 4 1904

This is the first reported case of tetanus that has recovered in this section of the country

THE YEAR'S SUCCESS IN TETANUS PROPHYLAXIS

Beginning with the Iroquois Theater catastrophe, just at the close of last year, a series of life-destroying disasters has followed with what seems to be unparalleled frequence and immensity The fire on the *General Slocum*, in East River, preceded but a short time the sinking of a steamer ladened with Scandinavian emigrants bound for this country Railroad wreck has followed railroad wreck, culminating in the Colorado disaster, which caused a loss of life almost unequaled in the history of railroad accidents In the face of these horrors, many of which were the plain result of negligence on the part of public or private officials, there is some relief to be found in the analysis of the annual tetanus epidemic, by which form of child-sacrifice we make our annual blood-offering to commemorate the independence of these our United States Last year we were able to collect 415 reports of convulsion-racked victims of the toy pistol and its allies, this year we rejoice at a list of only 105 And being a rare chance, we hasten to credit at least a part of these 300 saved lives to the efforts of public officers, to credit up on the side of the sheet opposite to the debit column of the Iroquois and the *Slocum*

In the analysis of the conditions existing during the epidemic of this year, the facts that develop seem to indicate that the improvement of this year, as compared with last year, is not due to natural causes, such as decreased abundance and virulence of the bacilli, but to a number of factors all produced by humane effort This is fortunate, for it holds forth hope that by a continuance of this effort the ground gained may be held, and still more improvement made in the future Tetanus was less frequent this year for two reasons First, less injuries were produced on the Fourth than usual, second, the injuries that were received were bett [illegible] cared for Both of these conditions were the outc [illegible] solely of a better understanding by public and pro [illegible] sion of the really tremend s danger that lies in Fourth of July woun [illegible] this understandin [illegible] credit must be given to t [illegible] th lay and medical [illegible] When, a year ago, The [illegible] an the collection of statistics on this subject [illegible] little appreciation of the real enormity of [illegible] t We were as much surprised at the hug [illegible] aths and 3,983 injured—as were nearly a [illegible] for no complete collection of these injur [illegible] ver before been made The labor and this work has been most abundantly repaid, for the effect produced far exceeded anything we had hoped for A definite basis of facts and figures was given for the many public-spirited citizens, physicians, municipal officers and editors who for years have been making earnest efforts to check an annual calamity which they appreciated more than did their hearers, and these facts and figures were so gruesome that none could fail to be impressed As pointed out in our article, the fruit of this was a universal publicity given by every paper in those portions of the country where Fourth of July is celebrated by explosives, which resulted in the passage and enforcement of laws aimed at the use of dangerous means of celebration, in the abandonment of "home treatment" of these wounds for care by physicians, and on the part of the physicians in a more thorough prophylactic treatment of Fourth of July injuries

The lesson and the danger of the future is clear It remains to be seen if the falling off in mortality will result in a falling off in precautions, as so often follows all movements depending on a public action As the gain has been made largely through the agency of the daily press, so it must be maintained by the same means, and medical men can do much to aid in this If before the coming Fourth local societies will pass resolutions calling attention to the need of enforcement of the laws bearing on the use of explosives, and the dangers of Fourth of July wounds as a source of tetanus, the papers will readily sound the alarm Much can be done in the way of aiding newspapers in preparation of articles on this subject by furnishing statistics and information from proper medical sources We have noted much good from just these measures during the past year Every effort must be made to see that the agitation of this year is repeated next June, or we may lose what has been gained, for the blank cartridge and the cannon cracker will be put on the market ready for sale wherever the police will permit

Another lesson of this year's epidemic is furnished in the results of prophylactic treatment and curative treatment The latter is, in the case of Fourth of July wounds, almost unavailing, as shown by a mortality of over 95 per cent Prophylactic treatment, on the other hand, is proven by repeated experience to be absolutely successful We have yet to learn of a boy whose blank-cartridge wound was thoroughly cleaned out under anesthesia and followed by an injection of antitoxin, who developed tetanus or suffered from the vigor of the treatment As proper treatment is so perfectly efficient in preventing lock [illegible] n the case of the boys who do [illegible] ckjaw af [illegible] ourth the question may be [illegible] t proper [illegible] is to blame?" For it is cer- [illegible] here ha [illegible] lect somewhere We can [illegible] t in th [illegible] we hope the neglect will [illegible] to l [illegible] the part of the patient [illegible] sso [illegible] f do something in thi- [illegible] lp [illegible] publicity through its [illegible] juries and their results, may it not start proper legislation aimed at the root of the evil—the manufacture and sale of dangerous explosives which are useless except for the celebration of the Fourth? Not until this is done will the situation be safe, and the initiation of such action would very properly begin with the American Medical Association.

DIABETIC NEURITIS.

The nervous system is peculiarly susceptible to the action of various chemical agents, whether introduced from without or generated within the body as a result of metabolic or infective processes. That in some instances the central, and in other instances the peripheral division, and in still other instances both divisions of the nervous system, should suffer under such circumstances, must be due to differences in chemical affinity beyond present means of determination. No doubt, isolated symptoms of neuritis have for a long time been observed in cases of diabetes, but it is, of course, only since knowledge on the subject of the former has become well defined that an understanding of the connection between the two has been possible.

The clinical phenomena to which peripheral neuritis gives rise are at times so much like those of locomotor ataxia that it is not surprising that the symptoms were for a long time attributed to disease of the spinal cord, and in this connection the question may be fairly asked whether there is not after all some relation pathologically between the gray matter of the anterior horns of the spinal cord and the motor nerves on the one hand and the sensory nerves and the posterior columns of the cord on the other hand.

In a recent communication, Dr. F. W. Pavy,[1] who has devoted much attention to the study of diabetes, and who was one of the first to describe the symptoms of neuritis as a complication of that disorder, discusses some of the varied phenomena of diabetic neuritis. He points out that cramp may occur in the absence of signs of neuritis, being especially marked when the amount of sugar in the urine is large, and he attributes the phenomenon to the direct effect of the sugar passing through the system on the muscular substance. The characteristic symptom of diabetic neuritis is a want of muscular co-ordination, without actual paresis. The ataxia is, as a rule, not so marked as under other conditions. At first the gait is unsteady and insecure, and somewhat like that of an intoxicated person, while later the patient may be unable to get along without the aid of a stick or the arm of a friend. The ataxic diabetic patient can maintain his equilibrium when standing with his feet together and his eyes shut much better than the tabetic. The ataxia may be unattended with sensory phenomena, while conversely these may be marked when the ataxia is slight.

Fibrillary contractions unattended with any sensation are sometimes visible over some muscles. They appear as wavy oscillations or twitchings beneath the skin. Hyperesthesia localized to different parts is frequently present. At other times there may be numbness, tingling, a sensation of pins and needles, and other paresthesiæ. Sometimes the soles of the feet are tender, so that walking is painful, or the patient may not feel the ground properly, or he may seem to be walking on pebbles or on pointed projections. Aching, deep-seated pains in the extremities, sometimes conjoined with lightning-pains, may be present, and often there is complaint of tenderness of the flesh and bones. The pain is usually worse at night than by day, and the patient may find difficulty in placing the legs in a sufficiently comfortable position to permit of sleep. Occasionally girdle-pain is observed. The knee-jerks are often abolished in cases of long standing, although they may later be restored with reduction in the amount of sugar in the urine. Should the vasomotor nerves be involved there may be local flushings and pallor of an abnormal nature, and the hands or feet may become hot and florid or blanched and cold. Trophic disorders also may result, for example, gangrene of the toes or perforating ulcer of the foot, cataract, loosening of the teeth, xanthoma, boils, carbuncles.

Diabetic neuritis is most commonly symmetrical in distribution, and the upper extremities are more frequently involved than the lower. All four extremities may, however, be affected together, or exceptionally the upper alone. Involvement of the right lower extremity, the right side of the body and the right upper extremity has been observed. Sometimes the disturbance is confined to a single nerve, such as the sciatic or the brachial. In some cases symptoms of angina pectoris have been noted, but these have yielded to treatment of the diabetes. Involvement of the third nerve, with ptosis and external strabismus, has been reported.

In the opinion of Dr. Pavy, the development of the neuritis complicating diabetes is attributable to the presence of sugar in the blood, and the treatment consists in measures directed to a reduction of the amount of sugar, especially careful dieting. In addition potassium iodid five grains, with ammonium bromid ten grains, has been administered thrice daily with benefit. Should these fail to bring about the desired result the continuous galvanic current may be employed, and when there is severe superficial pain a liniment containing aconite may be applied with advantage.

A NEW FORM OF THROAT INFECTION DUE TO AN ORGANISM OF THE OIDIUM GROUP.

The amount of bacteriologic work which has been done in the last few years on the various forms of angina is so great that one would expect that our knowledge of the different forms of throat infection would be fairly complete. Nevertheless, new varieties of throat infection have been described, notably the form due to the spirillum and fusiform bacillus of Vincent, and the occasional cases of tetragenus angina. That angina could be due to the group of organisms which cause ordinary thrush has hardly been suspected, though any bacteriologist who has worked with throat cultures can not have failed to note the relatively frequent occurrence of oidia and the French observers have reported a few cases in which this group of organisms played the part of secondary invaders.

---

[1] Lancet, July 2, 9, 1904.

In a recent article Oliver[1] has described a new form of throat infection, presenting characteristic clinical and bacteriologic findings, due to an infection with an organism of the oidium group. On the clinical side the disease presents a variety of pictures as it varies both in its course and in its severity. In children under twelve the disease usually assumes an acute form, while in adults the course is generally chronic, one of Oliver's cases having lasted for fourteen years. The symptoms first noted are those generally accompanying an acute infection, coryza, pain about the eyes, and aching of the back and limbs. These symptoms are accompanied with evidences of the local infection in the form of dry, paroxysmal cough and difficulty and pain in swallowing. The first objective signs are an intense hyperemia of the tonsils, uvula and pharyngeal wall, followed by great swelling of the tonsils and uvula, the cervical glands become enlarged and tender, and a thin, grayish-white, slime-like membrane appears on the tonsils. The temperature may remain normal or rise as high as 102 or 103 F. Subsequently a V-shaped membrane forms on the posterior pharyngeal wall, and this with the membrane over the tonsils becomes thickened, adherent, elevated, and of a pearl-gray color. About this time gray, elevated, hard, adherent patches appear on the tongue usually near the center, but occasionally all over. These are of pinhead size, but gradually increase until they may reach the size of a silver quarter. The patches are irregular, elevated, firm, furry to the touch, and can only be removed with difficulty and pain. The disease having reached its acme now tends toward healing the membrane disappears, the glands in the neck go down, and the general condition improves. In most instances, however, the tonsils and particularly the tongue are marked by ulcerations. In the tonsils these are generally situated at the top of the gland in the sulci, and are deep and punched-out in appearance. On the tongue the ulcers are irregular and quite deep, reaching into the submucosa. It is these ulcerations of the tongue which may remain for months and which characterize the chronic cases.

The bacteriologic examination of these cases shows the presence in cover-slips of numerous round or ovoid bodies from 6 to 8 micromillimeters in diameter, with double contour, and staining lightly except for a single chromatin granule at the thicker end. Attached to the oval body at the thicker end is a thread of varying length, which may or may not be jointed. The organism stains by Gram's method and all the basic anilin dyes. It is grown with difficulty at first, but when once obtained in pure culture can easily be reinoculated. It is pathogenic to rabbits, and in these animals the clinical picture of the disease can be reproduced quite closely. Of singular interest is the fact that a physician who worked at the laboratory bench where Oliver had autopsied his rabbits contracted the disease. While this form of throat infection has so far been described only in San Francisco, there is no reason to believe that it is limited to that locality, and it seems probable that like other new diseases as it is more carefully looked for it will be found to be more widely distributed.

BACKWARD CHILDREN AND EDUCATIONAL TECHNIC

An interesting experiment in educational methods which is attracting wide attention, is deserving of the special consideration of physicians. Very few are now persuaded that all men are born equal in the sense that intellectual qualities have been doled out with unfailing regularity. What certain pupils are able to accomplish with comparative ease, others of the same age and of the same social stratum may find very difficult. For these latter pupils attendance at school becomes a depressing routine, a constant source of worry and nervous unrest, and prone to be rendered still more unpleasant by intellectual tension out of school hours and the discouragement of the feeling of incapacity. How much of harm the attempt to cast all the pupils of each class in one mold has done, only those can realize who have seen delicate children run down every year under the strain of their school work.

The superintendent of the schools of Batavia, N. Y. found this problem of the weaker and slower pupils being compelled to compete with the physically stronger and intellectually more rapid workers crowding on him for solution. As described in a recent number of the New York *Independent*, there came to him an inspiration. "Let us," said he to the governing board, "put an end to this killing of children." His method was simple and rational enough. He suggested an extra teacher for every room, whose duty would be not to hear lessons, but to help those pupils who were falling behind in the class. Needless to say, this sort of help requires special tact and broad sympathy with children's minds, as well as a clear idea of the way in which pupils view things so as to recognize the source of their difficulties. The experiment was tried first in a single room, but the result was so strikingly beneficial both as regards the pupils themselves and the feelings of satisfaction on the part of the teachers, that what has since come to be called the "Batavian experiment" is now finding its way into many of the higher schools.

The most interesting feature of this experiment is that on the health of the children. While there was no doubt from the very beginning that it would be of service for the general scholarship of the schools, the hygienic feature was not expected to be quite so prominent

---

[1] California State Journal of Medicine vol ii No 8.

One mother, rejoicing over her boy restored to health and intellectual vigor, after she had seen him depressed and discouraged during the preceding year, declared the new experiment to be "a new phase of Christianity" It is especially satisfying to find that the success of the experiment has been pleasing to the powers that be in the school The president of the school board says The method of meeting our problem is not only a revelation, it is a revolution "

There are many physicians especially, who feel that too much is demanded of children in school at the present time There are many who are sure that the game is not worth the candle, since so many of the modern fads in education bear little relation to the real mental development or to success in life It would indeed be a consolation to find some way out of the anxious problem which physicians have had to meet in this matter of the education of more delicate children The fact that as many as six times the number of pupils remain to graduate at the high school in Batavia is apt to prove a better argument, however, for educators than any physical improvement may with the new system Let us hope that it will receive the recognition that it apparently deserves In any case it must be remembered that a child's health is much more important for its success in after life than any amount of education, however apparently successful our wonderful methods of educational development may be presumed to be

THE DEPARTURE OF DR. OSLER

While long expected, the announcement[1] of the intended departure of Dr William Osler to assume the regius professorship of medicine in Oxford University, conveys a sense of loss to the entire medical profession of the Western Hemisphere The change from the Johns Hopkins University, where he has been the shining light for so many years, to the famous old English university, is a change that does not alter Dr Osler's standing among the scientists of the world, because of the fact that he is almost as well known across the water as he is on this side By birth and education he was a Canadian, and in Canada was the commencement of his fame as a teacher and practitioner He came to the United States in 1884 to the University of Pennsylvania, and in 1889 he went to Johns Hopkins University, and has since been actively engaged in the affairs of that institution, for the past few years being its guiding spirit His extraordinary capacity for hard work, his keen insight into affairs, his marked success as a teacher of medical students, and his wonderful sympathy as a man among men, have centered about him a press of varied duties such as few men could successfully manage and fewer still carry for so long As a teacher, he has been most emphatic in upholding the principle that the art of medicine should be based on the most exact scientific knowledge obtainable In following out this principle in his own practice, his thoroughness has won for him the position which he holds—one of the foremost men in medicine to-day In every one of his varied duties he has been faithful

While typically representing the highest ideals in scientific medicine, he found time and inclination to lend a helping hand in all work that tended to uplift his profession He is an enthusiastic worker in the movement for the organization of the profession, and, burdened as he is by his other work, he does not hesitate to accept the position and perform the duties as councilor in his state when the new plan of organization was adopted by the Maryland Society In this he has set an example for those who feel that they are too much occupied with scientific work to meet on the common level and assist in the movement for the improvement of the profession This illustration of his devotion to the interests of his confreres shows that his actions were consistent with his high ideals as to the physician's duty

As one of the profession of Maryland, his loss will be especially felt His influence and example, his active participation in its activities, and his generous contributions to all its enterprises, have promoted immensely its morale His leadership has been felt and acknowledged by all Few men so well combine the qualities of leadership, tact, unselfishness, active interest in everything professional, and ability so conspicuous as to be recognized by all without jealousy

For some years Dr Osler has tried to arrange his work so as to avoid some of the tremendous pressure under which he labors His teaching, his hospital work his constantly increasing consulting practice, his participation in other professional affairs of local and national importance, have left him little time for his literary work The Oxford position is more of an academic one, involving less time-taking routine, and will, therefore, leave him free for the literary work which he is anxious to accomplish He undoubtedly hopes to utilize the immense amount of valuable clinical material which he has accumulated The ideal life in Oxford University is just suited to such work We congratulate both Dr Osler and Oxford University especially the latter

THE DOCTOR IN POLITICS

Every one should take an interest in politics, because it is one's duty as a citizen But every physician should be interested much more than the ordinary citizen, for his relations to the state are more important The people depend on him to suggest measures and methods for the sanitary and health legislation and for the care of the physically weak Evidently this view is held by a sufficient number of physicians in Texas to influence one of the parties, and to make it believe that it is to its interest to side with the profession The fourth plank in the Texas Republican platform is as follows

---

[1] THE JOURNAL news columns, Aug 20 1904

> We believe that the home for the old soldiers, that the asylums for the orphans, that our penitentiaries should be presided over by competent, honest and faithful servants, that our eleemosynary institutions should be sanitary, and the insane removed from our jails to proper quarters In trials for insanity there should be neither acquittal nor conviction without the interposition of a medical board

Would that the profession were influential enough to have such a plank in the platform of both parties in every state in the Union!

AMPUTATION STUMPS AND SATISFACTORY PROTHESIS

There is probably no class of surgical patients to whom the details of treatment have greater subsequent import than those requiring amputation of lower extremities, because the application of a satisfactory artificial leg depends directly on the character of the stump As this can be so greatly influenced by the operative and the almost equally important after-treatment, it should be an obligation for every surgeon to be exactly informed of the best methods F T Murphy,[1] in a very thorough study of this subject, from the viewpoints of the patient, the prothesist and the surgeon, has, by demonstrating the fallacies of many accepted procedures, and clearly indicating the surest means to the best functional results, forcibly emphasized the essentials of treatment, which, if closely followed, will reduce to a minimum the distress of an enormous number of unfortunates

ERYTHEMA CONTAGIOSUM

Under the name of erythema contagiosum, Escherich[2] has recently described cases of a disease which, in many ways, resemble the eruptive fevers of childhood The name was first given to the disease by Stricker of Giessen but Escherich states that he has observed it for a good many years, first at Graz, and later at Vienna It would appear that the disease was at first confounded with German measles The disease has an incubation period of from six to fourteen days, and appears in children, who are subjectively well, in the form of an intense redness and turgescence of the cheeks, which is often quite sharply limited by the nasolabial line, thus resembling erysipelas Less frequently the eruption on the face is in the form of flecks or gyrate patches In most cases there are also present on the forehead, the region of the ears, and on the extremities, scattered patches of bluish-red erythema which sometimes coalesce The eruption lasts from six to eight days, and then gradually fades, first on the face, then on the extremities There is no desquamation, and unpleasant sequelæ are not observed From time to time there have been described in this country epidemics of atypical eruptive fevers, usually considered to be atypical German measles It seems likely that the disease which Escherich describes may exist in this country, and it behooves the general practitioner, who is most likely to meet with such cases, to be on the lookout for it

UNPRECEDENTED MEDICAL ASPECTS OF THE WAR NOW IN PROGRESS

Warfare has lost its personal character, and is now merely wholesale butchery This fact is impressively demonstrated by a letter from Dr Paul Jacoby[1] of Orel, Russia, whose experience at the seat of war has shown that the battles and mine explosions affect men like great cosmic phenomena, in which the personal element is entirely lacking Danger, death itself, present themselves under new and strange forms, altogether different from the ideas of war to which we have been accustomed since the days when knighthood was in flower Our psychology has not adapted itself yet to the new aspect of warfare A cruiser which in less than two minutes sinks with 800 men on board, a skirmish in which 104 out of 107 of the horses are killed, an assault in which every assailant drops to the very last man, an assault over a surface known to be undermined by fifteen hundred mines, these things affect one like a tremendous earthquake or volcanic eruption Every physician knows that catastrophes of this kind breed psychoses, and the nervous condition of those who escaped from such catastrophes as the blowing up of the *Variag*, the *Petropavlovsk* and the *Hatsuse*, is similar to that of the survivors of some great cosmic upheaval Nervous disturbances and psycho-physical troubles should be treated at once, and on the spot, in conditions of absolute repose Some of the survivors of the battles and explosions at the seat of war were hurried away from the spot and sent home, the interminable railroad journey rendering their curable psychosis probably incurable insanity Jacoby has urged on the Russian Red Cross, and his suggestions have recently been put in practice, that certain barracks and tents should be set apart for such patients, to isolate them and render possible the restoration of their nervous balance The conditions of warfare all predispose to psychoses, under the most favorable surroundings, and the new forms of death—forms to which the mind is not accustomed—and the psychologic conditions which they create, must certainly have an influence on the psychophysical condition and on the pathogenesis of nervous morbidity among troops in active warfare They may perhaps, originate new morbid forms akin to the traumatic and hysteric neuroses of industrial origin In the campaign in Manchuria all these causes are cooperating with an unprecedented intensity, and the physicians at the seat of war have been so preoccupied with their surgical duties that these victims of the war have been neglected or sent home, thirty or forty days of railroad traveling being superadded to the other factors of their psychosis Jacoby refers the brutal acts and perversions of men in camp life to unrecognized psychoses generated by their environment The authorities and public opinion, however, are not always able to distinguish between a psychosis and a crime He refers to the recent suicide of General MacDonald as an instance in point The two armies now fighting in Manchuria have the sad privilege of inaugurating these new psychologic and psychopathic conditions of modern warfare with its character of industrial butchery by perfected processes No country in the world is prepared to face the exigencies of modern warfare perfectly, but fortunately the psychopathic victims of civilized war can be readily treated anywhere, even on the very battle-field Jacoby refers to his own experience at the Orel Asylum, where every year the summer months are spent by the inmates in temporary wooden shelters or tents while the buildings are being renovated The organization of a psychiatric department in the Red Cross service for troops during a campaign is a pressing necessity It is particularly needed when the campaign is remote from the centers of civilization, and, above all, in the tropics

Medical News.

ARKANSAS

Physician Pleading Self-Defense is Acquitted—Dr William L Parchman, Van Buren, charged with killing Charles Tolson, was found not guilty His plea was that Tolson made a movement as though he were about to draw a revolver

Unlicensed Itinerant Fined—An advertising itinerant specialist who attempted to ply his trade in Newport, was fined $25 and costs for failure to secure a county license The proceedings were instituted by the Jackson County Medical Society

State Board Reorganizes.—On July 12 the State Board of Medical Examiners met at Little Rock, and reorganized, electing Dr Adam Guthrie, Prescott, president Dr Ben L. Harrison Jonesboro, was appointed a member of the board vice Dr Charles R. Shinault, Little Rock, removed from first congressional district

State Society Election—At the annual meeting of the Arkansas Medical Society the following officers were elected Dr Joseph P Runyan, president, Drs John L Butler, Sheridan, Herbert H Canfield Siloam Springs, and Adolphus G Clyne, Bethel, vice presidents, Dr Richard C Thompson, Pine Bluff, treasurer, and Dr Charles C Stephenson, Little Rock secretary Little Rock was selected as the meeting place for 1905

Negro Medical Society—At the session of the Negro State Medical Association at Little Rock, Dr Hayward W Suggs Little Rock, was elected president, Dr Claude M Wade, Hot Springs, vice president, Dr Meaddoughs, Little Rock, secretary, and Dr George A. Flippin Pine Bluff, treasurer The association adopted resolutions that the colored race should have representatives on the State Board of Medical Examiners and State Board of Health

Lightle Not Dead.—Dr Richard G Lightle, Searcy, an account of whose tragic death by fire appeared in The Journal of June 4, and whose widow received $21,000 life insurance, has been found alive in Georgia and is to be extradited, and returned to Arkansas to be tried on the charge of attempting to defraud insurance companies Mrs Lightle, on being convinced that her husband was not dead, voluntarily returned the life insurance money to the five companies interested

CALIFORNIA.

Cornerstone Laid.—The cornerstone of the new College of Physicians and Surgeons of Los Angeles was laid with formal ceremonies August 13

New Medical Ward.—Through the munificence of a citizen of Pasadena, a medical ward has been provided for the Pasadena Hospital, which will cost about $15,000 The gift was conditional on the preservation of the incognito of the donor

Becomes a Part of University—At a meeting of the Board of Regents of the University of California in San Francisco, August 9 the intermediary department of medicine was taken over by the regents and will be reorganized into a regular department

Accident.—Dr Mary B Ritter, Berkeley, suffered fracture of the clavicle and two ribs in a runaway accident near New Almaden, and has intimated her intention of resigning the lectureship of hygiene in the University of California, on account of her injuries

Welch Delivers Lane Lectures—Dr William H Welch of Johns Hopkins University delivered the Lane course of ten lectures on "Infection and Immunity" before the faculty and students of Cooper Medical College and invited guests, in the five days beginning August 15

College to Have Library—Cooper Medical College, San Francisco, is now ready to erect the medical library building provided for in the will of Mrs Pauline C Lane, and the authorities of the college have petitioned the Superior Court for permission to sell the property bequeathed by her for this purpose

Dismissed and Convicted—The charges of practicing medicine without procuring a state license preferred by the State Board of Medical Examiners against Drs James Gerow, L A Cloutier and G W Winckfield of Oakland County, were dismissed, August 24, for lack of sufficient evidence to convict —— "Dr" W J Sylvester, San Francisco, convicted of practicing medicine without a license, was fined $100

ILLINOIS

The anti expectoration ordinance, which became effective in Joliet, August 15, prohibits spitting on sidewalks and in public places

Leprosy at Peru—A case of leprosy has been discovered in Peru The patient is a furnaceman at the works of the Illinois Zinc Company, is married, and has seven children The origin of the disease was not discovered

Smallpox.—Belleville has 9 houses quarantined and 3 patients at the County Isolation Hospital ——East St Louis, is reported to have 300 to 400 cases, 35 of the 38 patients at the isolation hospitals are from East St Louis ——Smallpox exists in a number of houses near the Illinois Central Station in Centralia and the railway company has asked the State Board of Health to enforce quarantine ——Peru has 15 cases and La Salle one case

Chicago

Personal.—Dr Alfred Schalek, after a long illness, has recovered and resumed practice ——Dr Thomas J Jackson sailed for Europe, September 1 ——Dr Ada A Latham was recently elected secretary of the American Microscopical Society —— Dr and Mrs Jacob Frank sailed from Hamburg for New York, August 28

Health Department Rejoices.—The Bulletin of the Health Department for the week ended August 27 is a song of rejoicing because the August death rate is phenomenally low, because the low mortality among infants and children continues, and because of the reduction in the cases of typhoid fever and acute intestinal diseases

Mortality of the Week.—The total deaths last week numbered 472, equivalent to an annual death rate of 12 76 per 1,000 or more than 16 per cent below that of the corresponding week of 1903 Acute intestinal diseases caused 102 deaths, consumption, 52, violence, 46, heart diseases, 30 pneumonia, 32, and Bright's disease 26

MARYLAND

Urges Vaccination—The State Board of Health is sending letters to the boards of school commissioners urging thorough vaccination of all school children before the term begins

Personal—Dr Charles G W Macgill, Catonsville, is visiting Richmond, Va.——Dr J R. Cullen, Catonsville, is visiting Camden, Del ——Dr Charles Owens, Sunnybrook, has gone to Port Norris, N J, to practice ——Dr Albert J Bossyns, of Mt Washington, has gone to the Pacific Coast, via St Louis

Baltimore

Personal—Dr Philip E Craig is seriously ill with typhoid fever

May Succeed Osler—The general belief in the profession in Baltimore is that Dr W S Thayer will succeed Dr William Osler, at the Johns Hopkins Medical School

Sings for Charity—Dr B Merrill Hopkinson has sent $59 35 for the Children's Fresh Air Fund, the net proceeds of a song recital given by him at Prout's Neck, Maine, where he is spending the summer

Seeks Mandamus.—Dr Campbell F Flautt has petitioned the Court of Common Pleas for a writ of mandamus compelling the Board of Medical Examiners of Maryland to issue him a permit to be registered as a physician An order was granted by the court, returnable September 10 Dr Flautt claims to have been a practitioner prior to Jan 1, 1898, the date of the law, and to be a regular graduate

MICHIGAN

Smallpox—It is reported that smallpox is prevalent in and around East Nelson and Pierson

Personal.—Dr William E Parker, Dowagiac is seriously ill with septicemia, due to an operation wound——Dr Myrtle E Lockwood, Battle Creek, has returned from Japan——Dr Raymond D Sleight, Ann Arbor, assistant in ophthalmology and otology in the University of Michigan, has resigned, and will practice in Battle Creek

Post-Graduate Instruction in Detroit—The Detroit Post Graduate School of Medicine has been incorporated with a capital stock of $5,000, by Drs Walter R Parker, Frederick W Robbins, Charles G Jennings, David Inglis, Burt R. Shurly, Charles D Aaron, Frank B Walker, Andrew P Biddle, Preston M Hickey, and Benjamin R Schenck The first session opened in the Detroit Clinical Laboratory building, September 1

Itinerant Wins First Suit—In the case of Max Jay Kraus, charged with practicing medicine in Michigan without being registered in the state, the jury returned a verdict of not guilty The defendant is one of an itinerant medicine company known as the Hot Springs Doctors," which has been taking $300 or more a day from the ignorant of Traverse City, and the prosecution was at the instance of the local medical association

July Mortality of Michigan—The total number of deaths for July was 2,510, or 65 more than the number for June, and 143 less than the number recorded for July, 1903 There were 520 deaths, or 20 7 per cent, of infants under 1 year, 143 deaths of children, aged 1 to 4 years, and 720 deaths of persons aged 65 years and over Important causes of death were as follows Influenza, 4, measles, 8, scarlet fever and whooping cough, 10 each, puerperal septicemia, 19, diphtheria, 24, typhoid fever, 28, meningitis, 36 pneumonia, 69, cancer, 156, diarrhea, enteritis, under 2 years, 206, tuberculosis, 211, and accidents and violence, 226 There were only 5 deaths reported from tetanus, a number much smaller than that for the corresponding month of 1903 No cause for tetanus was assigned, except in one instance, when a toy pistol was stated to have inflicted the wound that caused death There were 4 deaths from smallpox

MISSOURI

New Police Surgeons—Dr Herbert A Longan, Kansas City, has been recommissioned police surgeon, and has appointed Drs H. M LaRue, E J Morrow, and W L McKittrick as assistants

Will Now Distrust Burglars—Dr William Frye, Kansas City, who did not trust banks and kept his money with him, was visited by burglars who stole $6,500, and in addition attempted to asphyxiate the family by gas

St Louis Deaths.—For the week ended August 27, 193 deaths were reported to the health department, of which 21 were due to consumption, 26 to diseases of the digestive apparatus, 19 to heart disease and 17 to violence

Personal—Dr Frank S Vernon, Charleston, has been appointed assistant superintendent of the Farmington Hospital ——Dr W W Graves has returned to St Louis after an absence of four years in Europe——Dr Thomas J Baskett, Mexico, has been appointed coroner of Audrain County, vice Dr Charles T Varnon, deceased

NEW YORK.

Personal—Dr Grover Wende, Buffalo, has sailed for Berlin to attend the International Dermatological Congress——Dr Frederick C Peterson, Watertown, has moved to Syracuse

Regents Win—Dr Stanley Darlington, Buffalo, who was tried for practicing without a license and brought suit to compel the State Board of Regents to issue him a certificate, has lost again Darlington's attorney claimed the regents were prejudiced against him, but as it was shown that the regents offered to give him a hearing if he would deny under oath, their charges that he cheated at an examination and practiced without a license, the court said he should have taken their offer, and so denied him a writ of mandamus

State Hospital Report—The thirty third annual report of the Buffalo State Hospital has been issued The vacancy on the board of visitation, made vacant by the death of Dr Lothrop, has been filled by Dr William C Krauss While the hospital is fortunate to have been relieved of 200 of its patients by transfer to the Gowanda State Hospital, the reduction in number seems to have been temporary only The number of patients in the hospital is 1,822, during the year 429 were admitted, of these 94 were discharged recovered, 89 improved, 229 unimproved, and 104 died The percentage of recoveries to total number of admissions was 21 91

New York City

Contagious Diseases—There was reported to the sanitary bureau for the week ended August 20, 420 cases of tuberculosis, with 130 deaths, 224 cases of diphtheria, with 26 deaths, 120 cases of typhoid fever, with 20 deaths, 73 cases of measles, with 7 deaths, 54 cases of scarlet fever, with 5 deaths, and 24 deaths from cerebrospinal meningitis

Personal.—Dr Otto C Thum and party had a narrow escape from drowning on August 25 They had drifted out to sea in an unmanageable catboat When reached by lifesavers they were nearly exhausted from efforts at bailing, and had despaired of help——Dr George D Hamlen sailed on the *New York*, for Europe, August 27——Dr and Mrs Wendell C Phillips, who have spent the past month traveling, have returned to their summer home, Pawling

New Government Laboratory—The Department of Agriculture will establish a chemical laboratory for the examination of imported food products in the appraiser's stores building of the Treasury Department, which will be opened September 5 This is the first of a number of port laboratories to be established in order to prevent the introduction of impure food products into the United States Eighty per cent of the food importations arrive at New York, and samples from each cargo hereafter will be taken direct from the appraiser to the laboratory

Seek to Revoke Sydenham Charter—Charges have been made to the State Board of Charities against the trustees and managers of the Sydenham Post Graduate Course and Hospital, charging that the physicians who joined the staff had to pay a certain amount down and a stated sum monthly It is also charged that this institution is conducted in an unsanitary unlawful, negligent and improper manner The officers of the institution declare that the charges are utterly groundless and are made by men who have been discharged

Fresh Air Medicine—The New York Association for Improving the Condition of the Poor has given over 3,100 mothers and children excursions for ten days, and nearly 17,000 day excursions this summer This work has greatly aided in keeping down the summer death rate among the poor The resources of St John's Guild have been severely taxed this summer, and the reason is given that never before has there been so much severe sickness among the poor children and babies The institution maintains a floating and a seaside hospital, and since its first trip, July 5, it has cared for more than 25,000 sick children

Death and Mortality Rate of Diphtheria—In the Boroughs of Manhattan and the Bronx, from 1893 to 1903, inclusive, the following tables, recently published by the department of health, are interesting

Period	Cases	Deaths	Mortality per cent.
1893	7,021	2,558	36 4
1894	9,641	2,870	29 7
1895	10,353	1,976	19 1
1896	11,399	1,768	15 4
1897	10,896	1,590	14 6
1898	7,593	923	12 2
1899	8,240	1,087	13 1
1900	8,364	1,121	13 4
1901	7,726	1,227	15 9
1902	10,429	1,142	10 9
1903	11,662	1 302	11 2

The use of diphtheria antitoxin was begun by the department of health, Jan 1, 1895, but owing to bitter opposition it did not come wholly into general use until 1898 Since Jan 1, 1895, immunizing injections of antitoxin have been administered to over 13,000 individuals, and of these 40, or 3 per cent, contracted diphtheria of a mild type, with one fatal termination Since 1895 the department of health has gathered records of 15,702 cases which had been injected with antitoxin, excluding the moribund cases, 1,138 died, giving a case mortality of only 7 5 per cent Cases treated early in the disease gave almost no mortality

OHIO

Hospital Incorporated—The June M Case Memorial Hospital, the site and building for which was purchased for $10,000, bequeathed by the late Mrs Case, has been incorporated

Accidents and Operations—Dr Nathan S Hatfield, Bowling Green, recently underwent a serious operation in a Chicago hospital ——Dr William H Buechner, Youngstown, who was recently operated on for an infected operation wound, is making a good recovery ——Dr James W Graham, West Williamsfield, tripped while alighting from a train, was run over and crushed his left foot, necessitating the amputation of the toes ——Dr Cary I Legge, Newark, fell, while making a professional call, broke a rib and sustained severe contusions

Continued Prevalence of Rabies in Gallia County—Despite the warm weather there seems to be no marked subsidence in the endemic rabies among the dogs, cattle and swine in and around Gallia County and the adjacent country A report recently made to the pathologic laboratory of the Ohio Hospital for Epileptics indicated that some fifteen or twenty dogs had within the last three months, developed rabies in a rural neighborhood less than a mile square Fortunately not a person was bitten by these dogs, which were promptly dispatched Because of the extensive prevalence of the disease, grave fears are entertained for the safety of the public when, with the advent of cool weather, even more active manifestations are to be looked for

Personal—Dr Ephraim J McCollum, the oldest practitioner of Tiffin, was recently entertained by the Seneca County medical Society, and presented with a silver water pitcher ——Dr Franklin H Lamb, Glendale has been made lecturer on physiology in the Miami Medical College, Cincinnati.——Dr McKendrie C Smith, health officer of Columbus, has received the additional appointment of sanitary expert, with a salary of $1 200, and the duty of preventing water pollution ——Dr George R Love, first assistant physician at the Toledo State Hospital, has resigned and will take up general practice in Toledo ——Dr Charles C Walker Cleveland, sailed, August 18, from San Francisco, for his mission post at Wakawn, Siam ——Dr Thomas J Arundel, Youngstown sailed for Europe August 20 ——Dr H. Stow Garlick has been appointed surgeon to Battery B, Ohio N G, Cincinnati, vice Dr William H. Rothert resigned.——Dr Robert C Rind, Springfield, has been appointed chief surgeon of the Springfield Troy and Piqua Railway ——Dr Isaac D Jones, Walnut Hills, Cincinnati, returned from Europe, August 22

GENERAL

Dr Goodhue Improving—Dr E S Goodhue, Holualoa, Hawaii, who was seriously injured in a runaway while making calls July 16, is slowly improving One rib and the left shoulder were broken, besides other injuries

Dr Millican Goes to St Louis.—Dr Kenneth W Millican has resigned the position of associate editor of the *New York Medical Journal* which he has held since 1898 in order to assume the editorship of the *St Louis Medical Review*, the duties of which he takes up shortly

The Union of Old German Students in America will entertain the German scientists who attend the St Louis Congress of Arts and Sciences, at a "Kommers" in Arion Hall, October 8 Most of the eminent guests are medical men Further particulars may be had of Dr A Ripperger, secretary, 50 West 130th Street New York City

American Roentgen Ray Society—The fifth annual meeting will be held at St Louis September 9, 10, 12 and 13 The sessions will be held in the morning only, at the Louisiana Building, 911 N Vandeventer Ave The afternoons, evenings and the intervening Sunday will be left open for general sight seeing Hotel headquarters of the society will be at the Grand Avenue Apartments, Grand Avenue and Morgan Street An exhibit of the *x* ray apparatus will be a feature of the meeting

Ohio Valley Medical Association—The sixth annual meeting will be held at Evansville Ind., November 9 and 10 This association has for its boundary Kentucky, Indiana, Illinois and Ohio and has a membership of 300 The association stands for a higher standard in medical education, for a decrease in the number of medical schools to our needs, for a uniformity in the requirements to practice medicine in the various states for a reciprocity between the states and for a closer bond of friendship between the members of the profession All physicians who are in good standing in their county and state societies and who are thus agreed will be most cordially welcomed at the meeting Dr A J Lieber, Henderson Ky, is secretary of the association.

FOREIGN

Eiselsberg Declines Invitation to Berlin Chair—The chair of surgery left vacant by König's retirement after the completion of the model surgical clinic under his supervision, was offered to Professor von Eiselsberg of Vienna, with a tempting salary He does not care to leave Vienna, and has declined the offer

Completion of the Great Policlinico at Rome—Millions have been spent during the last few years at Rome in the construction of a great modern hospital, to be a model in every respect Medical visitors to Rome have all commented on the vast scale and fine appointments of this new institution, with its spacious surroundings, apart from the heart of the city It was formally inaugurated, August 4, and 500 patients from the other hospitals were transferred to the completed wards of the great Policlinico Umberto I," as it is to be called Three of the pavilions are devoted to surgery, seven to general medicine, and one to contagious diseases Each pavilion has a capacity of 80 beds The pavilions are separated by very wide and long galleries The appliances for heating lighting ventilation, etc, are according to the latest and most approved systems, and there have been several innovations in various lines The operating in one of the surgical amphitheaters is done in a glass compartment, the spectators without, able to see through the glass what is being done, while absolute asepsis prevails around the operating table The opening of the new hospital relieves the older hospitals and enables them to be set apart for certain classes of patients thus specializing them to a certain extent

LONDON LETTER

Cancer in Wild Animals

At the third meeting of the general committee of the Cancer Research Fund, the annual report which was read contained an account of most important work, and brought to light several facts which have a fundamental bearing on several of the crucial problems of cancer, and give definite indication of the line of future inquiries An extensive series of tumors from various domestic animals has been examined, many from lower vertebrates, including 14 cases of carcinoma in fish Two cases of malignant growths in fish are of special interest because they were derived from marine fish living in a state of nature A similar interest attaches to a spheroidal celled carcinoma discovered in a wild mouse These are the first fully authenticated cases of cancer in wild animals Upward of 2,000 specimens were examined, derived as follows Human, 266, horse 116, cow, 99, dog, 247 cat, 43, pig, 8, frog 6, bird, 13, mouse, 850, fish, 80, rat, 28, rabbit, 32, sheep, 8, goat, 7, bull, 1, miscellaneous, 329 'The general results obtained may be summarized thus Cancer has been found to pervade the whole vertebrate kingdom and to present constant fundamental characters The great diversity of the food, habitat, and conditions of life generally shows that such external agencies have no causative influence. The histologic characters, methods of growth and the absence of specific symptomatology lead to the conclusion that the causative factors must not be sought outside the life processes of the cells Growth after transplantation is possible in the bodies of animals of the same species Certain cells of malignant growths of man and animals were found to present nuclear changes similar to those by which the sexual cells are prepared for fertilization and the fusion nuclei in a manner equivalent to conjugation has been repeatedly demonstrated in transplanted tumors of the mouse, and has acquired increased significance from the discovery of the like phenomenon in a primary tumor from man If it should be generally established that cell conjugation takes place this would afford a harmonious explanation of all their features and the initiation of the cancerous cycle Under the heading of 'Statistical Investigations" the report furnishes a large amount of information and shows that certain popular beliefs as to the immunity of certain countries or races of men can not be sustained. Specimens have been obtained from the natives of regions of Africa in which cancer had not been discovered before The report of the treasurer appeals for more support Even with the aid of Mr W W Astor's munificent contribution of $100 000 the income does not meet current expenses

DUBLIN LETTER

Dublin Hospitals

As certain Dublin hospitals receive government grants, they are each year inspected by the board of superintendence. The annual report of this board is usually of some interest, for the statistics as to income expenditure and work The report is itself usually of a somewhat perfunctory nature, but this year, the board having apparently puzzled their brains to find something novel to write about, give a discursive and rather silly lecture on the application of *x* rays and other rays to medicine and surgery It is of course obvious that no general hospital is properly fitted unless it contains an *x* ray department and the board wastes its breath in laboring this point But when they also suggest that "necessity exists in every well equipped hospital for the installation of an apparatus for the use of the Finsen treatment," they are suggesting a very improper extravagance The Finsen treatment is as yet in its probationary stage, and it would be as foolish as it would be unnecessary for each of the very many small general hospitals in Dublin to incur the large expense such an outfit would demand The requirements of the city, as regards Finsen treatment, are quite adequately met by the hospitals which already are furnished with the apparatus The reports on the individual hospitals are in the usual complacent style of indiscriminate praise or mildest possible censure To read them one would think that each of the hospitals was managed in a perfectly satisfactory manner, an opinion very far from being justified For instance, we find no notice taken of the fact that the outbreak of smallpox with which Dublin was troubled last year, took its spread from the imperfect disinfection practices in a fever hospital where one imported case had to be treated In the report on this same hospital there is no mention made of any precaution being taken to prevent secondary infection, yet it is notorious that secondary infection is there very common Similarly the board of superintendence do not draw any attention to the fact that it is a by law of another of the hospitals they have supervised that any official of the hospital taking part in, or conniving at, any examination of a dead body in the institution is *ipso facto* dismissed Yet, if government superintendence is to do any good, it should aim at correcting such faults in management as these

Presentation to Professors Coffey and Ryan

An interesting ceremony took place a few days ago at the Catholic University School of Medicine, when the faculty, with a number of past and present students, met to present Dr Coffey and Dr Ryan tokens of friendship and regard on the occasion of their approaching marriages Both men stand high in the esteem of the profession as successful and inspiring teachers, as well as for their personal qualities, while their contributions to the sciences—physiology and chemistry—which they respectively teach, maintain the reputation of the Dublin school

Health of Dublin

We are so used to regarding Dublin as one of the most unhealthy, cities in Europe, if not indeed the most unhealthy, that it came as a pleasant surprise to us to learn recently that the death rate was approaching the figures that obtain in other cities in the kingdom In one week indeed the rate ran as low as 16 7 per thousand, but unfortunately the improvement was only temporary The real cause of the high mortality in Dublin is the fearful condition of the tenement houses, in which the majority of the poorer classes live, and to grapple with this serious problem no attempt has yet been made

The Irish Medical Association.

The annual meeting of the Irish Medical Association, which was held here recently was occupied chiefly, as might be expected, with the demands for reform in the Poor Law Medical Service Though progress seems slow there is no doubt that the public is at last being persuaded that the present system is bad Mr Tobin has succeeded Dr Leonard Kidd as president of the association

International Congress of Arts and Science

WASHINGTON, D C, Aug 26, 1904

To Members of the Medical Profession —The organizers of the International Congress of Arts and Science, to be held at the Universal Exposition, St Louis, Sept 19 to 25, 1904, desire to invite the special attention of your profession to the unexampled opportunity which it offers to meet and hear a great number of eminent men of learning It is expected that more than three hundred eminent scholars of Europe and America will deliver discourses in the various departments and sections of the congress, and that several hundred shorter communications will be made by those present Among the foreign members of the profession who have accepted invitations to speak are Profs Brunton, Semon, Ross, Celli, Orth, Liebreich, Allbutt, Kitasato and Escherich Dr William Osler is chairman of the department

It is the desire of the directors of the fair and of all concerned in the organization that professors and instructors in our colleges and universities, and members of the learned professions generally, shall, so far as possible, do honor to our distinguished visitors by attending the meetings of the congress For this no fee is charged and no formality is necessary except enrollment on arrival It is, however, desirable to apprise Mr Howard J Rogers, director of congresses, Universal Exposition, St Louis, in advance, what departments of the Congress one desires to attend A program of its proceedings, with such other instructions as may be necessary, will be sent by Mr Rogers on application

SIMON NEWCOMB,
Chairman of the Organizing Committee
NICHOLAS MURRAY BUTLER,
Chairman of the Administrative Board

Method of Making Yellow Oxid Ointment.

BURLINGTON, IOWA, Aug 23, 1904

To the Editor —I notice a suggestion in Dr Bulkley's "Notes on Ointments," which I consider inadequate, if not misleading Otherwise we would not have the perennial complaint from ophthalmologists that it is hard to get satisfactory "yellow oxid ointment" This suggestion is that gritty substances should first be rubbed up with a few drops of oil in a mortar to make a fine paste I object to the use of the mortar because a sheet of plate glass and a spatula are better Only with the latter can one be absolutely sure that no gritty particle is missed No oil or water is needed The spatula, holding a modicum of the base (just enough to do it), picks up the grits, which are then rubbed out until they can be rubbed no farther, and the spatula cleans itself Not only can every particle of grit thus be felt, but one can also hold the plate up to the light for inspection with a magnifying glass The base is now added in mass and the mixing completed with the spatula I had the pleasure of demonstrating this method to the Section on Ophthalmology, producing a perfect yellow oxid ointment, at the Denver session of the American Medical Association H B YOUNG

North Carolina's Early Law on Practice

KINSTON, N C, Aug 24, 1904

To the Editor —I noticed in THE JOURNAL, August 13, that you state in an editorial that Illinois had the first effective law regulating the practice of medicine North Carolina really should have that distinction, her law having been passed in 1857 The remarkably high standing of her profession, which we believe to be higher than any other state, on an average, is due to her splendid medical laws, which have been "effective more than a quarter of a century"

JAMES M PARROTT,
Member of the Carolina State Board of Medical Examiners

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed Queries for this column must be accompanied by the writer's name and address, but the request of the writer not to publish his name will be faithfully observed

ARISTOCRACY IN MEDICINE

B writes In an issue of THE JOURNAL published within the past year attention was called to the fact that the degree of M D had a very wide range of value It was pointed out that all classes of medical schools, the bad, the good and the best, conferred the same degree, and that unfortunately, no means existed whereby the value of the M D could be gauged All were M D s all were physicians This being so, I should like to have a careful consideration and an opinion on the following question Is it unprofessional for a physician to insert in very small type on his sign the degrees he has and from what institutions the lettering to be invisible except on close inspection This additional in formation (for example A B, Princeton M D, Harvard) is certainly of benefit to the public. It shows that the physician has obtained a good general education and that he has equipped himself for the medical profession by at least eight years of study, and therefore has some claim to the confidence of the community He should get some credit for his long and thorough course and this is a way of making an M D mean something Look at the difference in time One man goes through the grammar school and then studies medicine four years The other goes through the grammar school then high school four years then college four years, then medical school four years then hospital two years Why should he not demonstrate that four does not equal (4+4+4+2) 14 I think the day will come when this negative demonstration will be made by all those who can do so and that too by means of the sign I can see nothing unprofessional in it On the other hand I think it is a suggestion which could be widely adopted to the profit of the physician the profession and the public Please do not reveal my name in any way or to any one

Answer —The question raised is not new Custom decrees that t is not good taste to place on one s sign the name of one s school of graduation. To run counter to this custom would not be unprofessional but we think that it would be unwise Our correspondent overlooks in his letter the fact that all sorts of physicians the bad the good and the best are at times graduates from the very best of medical schools In the last analysis every physician must rise or fall on his own individual ability and character It can not be otherwise The assumption that a physician might command success on the reputation of his alma mater refutes itself If such were the case the cleverest wicked men among those contemplating the study of medicine would attend solely those schools whose reputation would insure to the holders of their degrees professional standing and success Nothing would be gained in the end by the adoption of such a custom while many good and capable men who have been forced by one or other circumstance to attend a school of low degree would suffer unmerited ostracism. The school does not make the physician Our correspondent s plan would make it too easy for the lazy and the indifferent, who were just capable of scraping under the minimum requirements of the fourteen years of preparation The profession has already adopted the better course viz having the state require a certain standard of personal general and professional education Unfortunately our own medical schools while on the whole worthy of all admiration have shown that unaided they can not maintain the required standard The best feel the competition of the poorest. There is many a medical school whose degree granted a decade or two ago was more worthy of respect and confidence than that of the same school to-day and vice versa In this country at least our profession must be democratic and not aristocratic as proposed by our correspondent

EFFECTS OF FORMALIN ON TISSUES

Dr. Frederick C Murray Cedar Rapids Iowa writes Some months ago I read a brief reference to the action of formaldehyd on the abdominal contents or other tissues of the recently dead body When formalin embalming fluid was used certain marked changes took place in certain tissues, which simulated pathologic lesions and might lead to errors in postmortem diagnosis Would it be presumption to suggest provided information is definite and reliable as to formaldehyd s action under such circumstances that some publicity be given to it, perhaps among Minor Notes In my limited experience it has seemed to me that this action of formalin embalming fluid has very seriously confused the findings at several postmortems recently witnessed so that I feel I am not the only person who needs enlightenment on this possible source of error

Answer —Embalming with formaldehyd alters the consistence of all the organs greatly as also their appearance making accurate diagnosis difficult for the most expert, and in many respects impossible The chief difficulties that might be mentioned are the following By vigorous use of the embalming trocar the undertaker usually punctures the stomach and intestines full of holes thus emptying their contents into the peritoneal cavity and making difficult or impossible any search for suspected perforations or chemical examination of their contents in suspected poisoning cases The peritoneal coat is so roughened that recognition of an early or acute form of peritonitis is usually impossible Firm contraction of the muscular walls of the intestine occurs in response to the stimulus of the formalin so that local areas of contraction appear that may be mistaken by the uninitiated for strictures Stomach and intestines are hardened into such a leathery condition that there are some technical difficulties in their examination but not insurmountable All the organs that the formalin penetrates are made very hard, almost woodeny in consistence but as the distribution of the hardening fluid is often very irregular some confusing conditions may appear The hardening of the kidneys is very easily mistaken for the induration of a chronic nephritis and similar errors may be made in the case of the liver and spleen The coagulating action of the fluid practically precludes the detection of cloudy swelling and other finer changes. In the lungs there are especial difficulties, because a soft exudate may be so hardened as to change its appearance entirely and so a hypostatic edema may be mistaken for a pneumonia A bronchopneumonia of simple type is often indistinguishable from a tuberculous lesion under these conditions On the other hand hardening of the brain by formalin if the injection has been sufficiently efficient to do this is often of considerable aid in removing the brain and in its examination, making it much easier to ascertain relations of lesions etc It is, indeed a recognized procedure in autopsies to inject the carotids with formalin for this very purpose as a hardened brain can be removed with much less danger of producing artefacts than can a fresh one And also the histologic findings are often very beautiful in tissues taken from these bodies in which every cell while still warm has been quickly surrounded by the hardening fluid although with some of the fluids used there is sometimes a heavy precipitate formed that is very troublesome Many lesions of the parenchymatous organs should be left for diagnosis in these embalmed bodies until after microscopic examination It is hardly necessary to add that one of the most serious objections to embalming of bodies is that it precludes absolutely any bacteriologic examinations which in many cases are by far the most important part of the autopsy

METHODS OF PRODUCING EUTOCIA

A of Michigan writes Kindly inform me whether there is known to the medical profession any remedy which if given during pregnancy will cause the pelvic bones to loosen up or the pelvic muscles to relax and thus delivery be made easier We have here a brother practitioner who advertises that while East he became acquainted with such a remedy and that the same is not yet revealed unto the medical fraternity who have not been East to learn about it. Now this would all be absurd if people would only think but many do not make such an effort and not a few have already begun to take this remedy A good friend of mine whose wife is pregnant came to me a few nights ago and asked me about this new discovery and whether it were true that our brother has a monopoly or the article in this part of the world Will you kindly state in The Journal whether there is any such remedy?

Answer.—Our correspondent seems to possess the only satisfactory means of combating the absurd claims of his humbugging colleague—an indulgent sarcasm It is now generally although not universally, admitted that there is during pregnancy a slight increase in the mobility of pelvic articulations due to an increase in the succulence of the ligaments and capsulary membranes A similar change in the soft parts composing the pelvic floor also favors the formation of the normal obstetric canal These changes are subject to slight physiologic variations but we know of no pills or powders that affect them Various methods of making the child bearing process easier in cases where the pelvis is normal in size and possible when the pelvis is contracted have been sought from time to time They generally aim at reducing the size of the child or making its bones more pliable. The dietetic treatment is most common Sometimes the mother has been partly starved sometimes she is kept on a fruit diet and more recently Prochownik has proposed an anti obesity diet for the last two months of pregnancy to prevent the accumulation of fat by the fetus Occasionally drugs have been given which disturb the appetite and thus interfere with the growth of the child by lessening the nutrition of the mother All such attempts to interfere with Nature except perhaps a careful use of Prochowink s diet are apt to be harmful if they are not simply useless and absurd

PRIVATE PAID QUIZ COURSES

Dr D W Evans Scranton Pa writes There is one curse that should be blotted from the medical schools of this country and that is the private paid for quiz course given by the teacher but which is usually conducted by a super or perhaps a super number two otherwise known as the men next to the professor First of all it is cash in hand and the poor student who has not the cash feels at once the cutting lance of class legislation (for the faculty says nothing which means O K) and many a student poor financially has been made dishonest as well as discouraged by such proceedings When it is as generally known as is the unchangeableness of the laws of the Medes and Persians that if you take my course you pass my chair A little time ago while taking in some of the medical schools I noticed in one city in particular it was common and I took note in one of the oldest and most dignified institutions in America had not less than four quiz courses posted and each one in such a conspicuous place and so large and plain that they would even scare the dispensary patient who happened to run against them and especially would it scare him when $100 was the price a larger sum than is paid for an entire year s tuition in some of the best institutions of the land And all this for one branch why not for all branches and not have a school at all? Then other things being equal none but the wealthy could even entertain an idea of medicine let alone support themselves while going through as have hundreds of young men who are our brightest and keenest men to-day I say abolish it. Devise some other method of robbing the student and not under the cloak of a professorship I trust the Council on Medical Education of the American Medical Association and other organized educators will investigate and abolish one of the remnants of feudalism the board wastes its breath in laboring this point But when they also suggest that "necessity exists in every well equipped hospital for the installation of an apparatus for the use of the Finsen treatment," they are suggesting a very improper extravagance The Finsen treatment is as yet in its probationary stage, and it would be as foolish as it would be unnecessary for each of the very many small general hospitals in Dublin to incur the large expense such an outfit would demand The requirements of the city, as regards Finsen treatment, are quite adequately met by the hospitals which already are furnished with the apparatus The reports on the individual hospitals are in the usual complacent style of indiscriminate praise or mildest possible censure To read them one would think that each of the hospitals was managed in a perfectly satisfactory manner, an opinion very far from being justified For instance, we find no notice taken of the fact that the outbreak of smallpox with which Dublin was troubled last year, took its spread from the imperfect disinfection practices in a fever hospital where one imported case had to be treated In the report on this same hospital there is no mention made of any precaution being taken to prevent secondary infection, yet it is notorious that secondary infection is there very common Similarly the board of superintendence do not draw any attention to the fact that it is a by law of another of the hospitals they have supervised that any official of the hospital taking part in, or conniving at, any examination of a dead body in the institution is *ipso facto* dismissed Yet, if government superintendence is to do any good, it should aim at correcting such faults in management as these

Sir William Mitchell Banks, M D University of Edinburgh, 1864, gold medaler of that year, afterwards demonstrator of anatomy in Glasgow, and in 1869 Fellow of the Royal College of Surgeons of England, and one of the most eminent anatomists and surgeons of Great Britain, died at Aix la Chapelle, August 9, aged 61 He was consulting surgeon of the Liverpool Royal Infirmary and professor and emeritus professor of anatomy at the University of Liverpool He took an active interest in the organization of the Liverpool School of Medicine In recognition of his services to surgery and science he was knighted in 1899 He was particularly interested in the study of cancer and delivered the Lettsomian lectures on Cancer of the Breast in 1900 As a teacher of anatomy and as a clinical professor he was unequaled in Great Britain He was a member of the British Medical Association and president of the Lancashire and Cheshire Branch He was president of the Liverpool Biological Society and of the Liverpool Medical Institution vice president of the Medical Society of London, and a corresponding member of the Association of Military Surgeons of the United States

Book Notices.

MATERIA MEDICA PHARMACOLOGY AND THERAPEUTICS INORGANIC SUBSTANCES By Charles D F Phillips M D LL.D (Abdn. and Edin) F R S (Edin) Hon Fellow Medico-Chirurgical College. Pennsylvania Member of the Academy of Medicine of America Examiner of Materia Medica University of Aberdeen etc Third Edition. London. New York and Bombay Longmans Green & Co

This edition has been thoroughly revised and many pages entirely rewritten In the first chapter the author gives an excellent résumé of the recent investigations in the action and uses of oxygen and ozone in medicine We note also the chapter devoted to water its action and uses, and can say we know of no general treatise which has given this subject such complete and practical consideration Detailed description of the many and varied uses of water in the domain of therapeutics is lacking in works of this character This chapter will appeal to many who have only a most general concept of the use of water in disease Full consideration is given both the internal and external uses of water, including sea bathing, medicated waters, describing particularly the value of many of the famous natural waters We commend the general classification of subjects based on the chemistry of the elements and drugs The gases and non metallic elements are first considered, then the halogen group with reference to the newer derivatives from iodin, the glycerophosphates, cacodylates, etc The acids are next in order and the text completed by the description of the metals The author has quoted liberally from the recent literature, making the book up to date The method of description of a drug and its preparations is systematic and complete, the physical characters, the tests, the physiologic action, toxicology and therapeutic application are each treated of in detail Reference is made in the most of the chapters to the synergists as well as to the antagonists and incompatibles This will be found of practical use to the beginners The most important drugs, for example, arsenic, mercury, etc, are fully described and especial attention is given to the various diseased conditions they are used in and to the preparation most indicated We would criticise the index, believing it to be of value as a reference for remedies in the treatment of disease, but very incomplete and of practically no value as a reference for the study of the individual drug The index includes references made to drugs in the companion volume which is not yet published A fuller index limited in its reference to this volume would be far more serviceable

INTERNATIONAL CLINICS A Quarterly of Illustrated Clinical Lectures and Especially Prepared Original Articles on Treatment, Medicine. Surgery Neurology Pediatrics Obstetrics Gynecology Orthopedics. Pathology Dermatology Ophthalmology Otology Rhinology Laryngology Hygiene and Other Topics of Interest to Students and Practitioners. By Leading Members of the Medical Profession Throughout the World Edited by A. O J Kelly A.M. M D Philadelphia With Regular Correspondents in Montreal London Paris. Berlin. Vienna Leipsic, Brussels and Carlsbad. Volume II. Fourteenth Series 1904. Cloth Pp 300 Price, $2.00 Philadelphia J B Lippincott Co. 1904.

The excellency and value of this volume is in keeping with previous publications in this series It contains many articles of more than usual interest and notable among these are the series on diseases of warm climates contributed by Drs Mason McCrae, Jarvis, Smith and others The papers on the treatment of arteriosclerosis by Nichols and Bierring, one on the "Utility of Digitalis in Heart Disease" by French, a medical clinic by Billings, and an article on "Bronchopneumonia in Children" by Abt, are also worthy of mention The volume abounds in an unusual number of illustrations, especially the series of papers on diseases of warm climates Illustrations always are valuable because they serve to elucidate a point far better than could be done by the best description Eye pictures excel word pictures, and every article ought to be illustrated as much as is possible

NORMAL HISTOLOGY By Edward K Dunham PH B M D Professor of General Pathology Bacteriology and Hygiene in the University and Bellevue Hospital Medical College, New York Third Edition Revised and Enlarged Illustrated with 260 Engravings Cloth Pp 332 Price $2 75 New York and Philadelphia Lea Brothers & Co 1904

This is the third edition of a work which is deserving of more recognition than has been accorded to it in the past The arrangement of the subject matter is excellent, the sequence being such as to lead the student up gradually, beginning with the cell and ending with the organs of the special senses The introduction is excellent but has hardly gone far enough to prepare the student adequately for what is to follow Still it may be assumed that the student has studied embryology and biology prior to his entrance in the medical college, and a more extended introduction would therefore take up space which can be devoted more profitably to a discussion of histology itself The chapter on histologic technic is concise and to the point, not attempting to confuse the student by presenting many methods of tissue preparation and staining The book abounds in excellent illustrations, most of which have been taken from other works on histology

THE SURGERY OF THE HEART AND LUNGS A History and Résumé of Surgical Conditions Found Therein, and Experimental and Clinical Research in Man and Lower Animals with Reference to Pneumonotomy Pneumonectomy and Bronchotomy and Cardiotomy and Cardiorrhaphy By Benjamin Merrill Ricketts Ph B M D Cloth Pp 510 Price, $5 00 New York The Grafton Press. 1904

Those who are familiar with the large amount of experimental work on the heart and lungs which has been done by the author of this work will be very glad to have it all in book form One finds here, however, not only the experimental work which in itself is very interesting, but also practically all that has thus far been accomplished in this comparatively newer field of operative surgery The work is well illustrated by 87 plates almost all of which are new and original, and the bibliography is very extensive, but so subdivided and distributed throughout the work as to facilitate ready reference to any particular subject It is by experimental work that the border line of surgery is constantly advanced, and one can not help but find in this work much that is of real value as well as of great interest

The Public Service.

Army Changes.

Memorandum of changes of station and duties of medical officers, U S Army week ending Aug 27 1904

Whitcomb, C C asst surgeon granted one month and fourteen days leave

Baker Frank C asst surgeon left Ord Barracks Cal, en route to Fort Sheridan Ill, to take part in Army infantry competition

Appel Daniel M surgeon reports on thirty days' leave from date

Owen Wm O surgeon, reported at U S Army General Hospital Presidio of San Francisco for treatment and observation from sick leave

Raymond Thos U surgeon detailed to represent medical department of the Army at meeting of the American Roentgen Ray Society to be held at St Louis Sept 9 to 13, 1904 is revoked

Reno Wm W asst surgeon, now on duty at St. Louis is detailed to represent the medical department of the Army at the meeting of the American Electro-Therapeutic Association to be held in that city Sept 13 to 16 1904

Johnson R W surgeon now on duty at St. Louis is detailed to represent the medical department of the Army at meeting of the American Roentgen Ray Society in that city, Sept 9 to 13 1904

Devereux J R asst surgeon left Fort Meade S D on ten days leave of absence

Bantlett C J asst surgeon assigned to duty at the Army and Navy General Hospital Hot Springs Ark

Raymond Thos U surgeon order relieving him from duty at Louisiana Purchase Exposition St Louis and assigned to duty at Fort Assinniboine Mont is revoked

Marrow Charles F asst surgeon assignment to duty at Manassas Va. during maneuvers is revoked

Baker Frank C asst surgeon assigned to duty at Manassas Va during maneuvers

Banister Wm B surgeon left Jefferson Barracks Mo en route to San Francisco with recruits

McCulloch C C asst surgeon will take charge of the office of the chief surgeon Department of the East during the absence of Major John L Phillips surgeon at the maneuvers at Manassas Va acting chief surgeon

Noble R E asst. surgeon granted fourteen days leave of absence.

Mabry William C contract surgeon arrived at the camp of the organized militia of Ohio at Athens for duty

Hussey Samuel W contract dental surgeon granted leave of absence for two months from Fort Snelling Minn

Ware William H contract dental surgeon granted leave of absence for two months before going to duty at Fort Logan Colo

Woods, Oscar W contract surgeon granted leave of absence for two months from Vancouver Barracks Wash

Brooks John D contract surgeon left Fort Meade S D August 19 and arrived at Fort Crook Neb August 21 for temporary duty

Greenberg Harry contract surgeon granted leave of absence for one month.

Griffith Lewis T contract surgeon ordered from Troy N Y to Manassas Va for duty during the maneuvers

Voorhies Hugh G contract dental surgeon granted an extension of one month to his leave of absence

Navy Changes.

Changes in the medical corps U S Navy for the week ending Aug 27 1904

Kennedy R M surgeon detached from Naval Hospital New York and granted sick leave for one month

Huntington E. O surgeon detached from Naval Hospital Portsmouth N H and ordered to duty at the Naval and Marine Recruiting stations Chicago August 24

Braisted, W C surgeon detached from the *Relief* and ordered to the *Pensacola*

Guthrie J A P A surgeon granted an extension of leave for three months

Wilson H D P A surgeon ordered to duty at the Naval Hospital Portsmouth N H

Wise A H A A. surgeon detached from the Naval and Marine Recruiting Stations Chicago and ordered to duty with Naval Recruiting Party No 1 August 25

Duncan G F A A surgeon detached from the *Franklin* and ordered to duty with Naval Recruiting Party No 3

Dabney V A A surgeon ordered to duty with Naval Recruiting Party No 2

Lewis D O medical inspector commissioned a medical inspector from Jan 4 1904

Wheeler, L H asst surgeon detached from duty at the Naval Hospital Boston and ordered to duty as recorder Naval and Medical Examining Board Washington D C

Marine-Hospital Service

Official list of the changes of station and duties of commissioned and non commissioned officers of the Public Health and Marine Hospital Service for the thirteen days ended Aug 24 1904

Purviance Geo asst. surgeon general granted extension of leave of absence for one month from Aug 1 1904 on account of sickness

Williams L L asst surgeon general relieved from status of absent on leave and directed to assume temporary command of the Cape Fear Quarantine Station during the absence on leave of Asst surgeon B S Warren On the return of Asst surgeon Warren to resume status absent on leave

Williams L L asst surgeon general granted extension of leave of absence for fifteen days from August 18 on account of sickness

Bailhache P H surgeon granted leave of absence for seven days from Aug 14 1904 under the provisions of Paragraph 191 of the Regulations

Foster M H P A surgeon granted leave of absence on account of sickness for one month from Aug 18 1904

Fox Carroll asst surgeon granted leave of absence for three days under the provisions of Paragraph 191 of the Regulations

Schereschewsky J W asst surgeon to proceed to Philadelphia Pa for temporary duty in connection with the inspection of alien immigrants during the absence on leave of P A Surgeon Taliaferro Clark

Francis Edward asst surgeon granted leave of absence for seven days from Aug 8 1904 under the provisions of Paragraph 191 of the Regulations

Francis Edward asst surgeon granted extension of leave of absence for twenty one days

Warren B S asst. surgeon granted leave of absence for six days

Hunt Reid chief division of pharmacology granted leave of absence for six days from Aug 22 1904 under the provisions of Paragraph 210 of the Regulations

Walkley W S A A surgeon granted leave of absence for three days

Hallett I B A A surgeon granted leave of absence for four days

Bean L C A A surgeon granted leave of absence for five days from Aug 22 1904

Simonson G T A A surgeon, granted leave of absence for fifteen days from Aug 20, 1904

Grace J J A A surgeon granted leave of absence for thirty days from Sept. 23 1904

Loehrig A M pharmacist detailed to represent the service at meeting of American Pharmaceutical Association at Kansas City Mo Sept 5 to 10 1904

Brock G H pharmacist relieved from duty at Delaware Breakwater Quarantine and directed to proceed to St. Louis Mo and report to medical officer in command for temporary duty

Gibson R H pharmacist, granted leave of absence for thirty days from Sept 7 1904

O Gorman T V pharmacist granted leave of absence for thirty days from Aug 18 1904

Miller Charles, pharmacist detailed to represent the service at meeting of American Pharmaceutical Association at Kansas City Mo Sept 5 to 10 1904

Kolb W W pharmacist relieved from duty at the Savannah (Ga) Quarantine Station and directed to proceed to Washington D C and report at the Bureau preliminary to assignment to duty in the Hygienic Laboratory

Rogers Edward pharmacist, relieved from duty at Cleveland Ohio and directed to proceed to New York N Y (Stapleton) and report to the medical officer in command at that port for duty and assignment to quarters

Mason M R pharmacist granted leave of absence for fifteen days from Sept 1 1904

Southard F A pharmacist granted leave of absence for four days from Aug 8 1904 under the provisions of Paragraph 210 of the Regulations

Southard F A pharmacist relieved from duty in the Hygienic Laboratory Washington D C and directed to proceed to Cleveland Ohio and report to the medical officer in command at that port for duty and assignment to quarters

Spangler L C pharmacist, relieved from duty at the Tampa Bay (Fla) Quarantine and directed to proceed to Savannah (Ga.) Quarantine and report to the A. A surgeon in charge for duty and assignment to quarters

Van Ness G I Jr pharmacist relieved from duty at New York (Stapleton) and directed to proceed to Louisville Ky and report to the medical officer in command at that port for duty and assignment to quarters

BOARDS CONVENED

Board convened to meet at Washington D C Aug 25 1904, for N Y Aug 13 1904 for the physicical examination of a chief engineeer of the Revenue Cutter Service Detail for the board P A Surgeon A. C Smith chairman P A Surgeon C H Lavinder recorder

Board convened to meet at Washington D C Aug 25 1904 for the physical examination of a candidate for appointment in the Revenue-Cutter Service Detail for the board Asst. Surgeon General W J Pettus chairman Asst Surgeon A J McLaughlin recorder

Health Reports

The following cases of smallpox yellow fever cholera and plague have been reported to the Surgeon General Public Health and Marine Hospital Service during the week ended Aug 26 1904

SMALLPOX—UNITED STATES

Georgia Macon Aug 13-20 1 case

Seventy second Annual Meeting, held at Oxford, July 26 30, 1904

(Continued from page 625)

Total Enucleation of the Prostate

In this paper Mr P J Freyer described his results in his 110 cases of suprapubic prostatectomy, the patients varying in age from 53 to 84 and the prostates weighing from ¾ of an ounce to 14¼ ounces The majority of the patients had been dependent on the catheter for periods varying up to 24 years Nearly all were in broken health and many were apparently moribund and few were free from complication In three cases the disease was malignant One died twenty days after the operation, when the wound was practically healed The other two made fairly good recoveries Excluding these three cases there were 107 cases of complete removal of the adenomatous prostate, of which 97 were completely successful, the power of retaining and passing urine without the aid of the catheter being regained In only two cases did septicemia follow operation, and this Mr Freyer ascribed to an immunity acquired by the patients from long absorption of septic urine There were ten deaths, two from mania after the wounds had practically healed, one from heat stroke on the tenth day, when the patient was practically convalescent, one from coma due to absorption of toxins from the urine, which had set in several days before operation, one from pneumonia seven days after operation, one from heart failure six hours after operation, one from heart failure, one from interstitial nephritis, and two from septicemia In only four or five cases could the deaths be ascribed to the operation But accepting all the deaths, the mortality is only 9 per cent —about one fourth of the mortality from lithotomy at the same ages Mr Freyer claimed that his operation gave results far superior to those attained by any other method of treatment

Pseudo-Malarial Fevers

The Section in Tropical *Medicine was undoubtedly one of* the most important and well reflected the recent great progress in the knowledge of tropical diseases The President, Dr Alexander Crombie, delivered an opening address on "The Fallacy of Finality" He pointed out that while clinicians believe in the existence in hot climates of fevers of a continued type other than typhoid and malarial, bacteriologists do not Notwithstanding the official returns, which show an overwhelming majority of admissions for malarial fevers, he believed that "ague" is not the most prevalent type of fever in India The commonest type is what he has called "single paroxysm fever" The paroxysm may be of a few hours or few days' duration, but it is a single paroxysm and has no tendency to recur If it lasts a few hours it is called "ephemeral fever", if a day or two, "febricula", if several days, "simple continued fever" These attacks give no clinical evidence of periodicity such as would be caused by the life cycles of a parasite in the blood, and recovery takes place without administration of quinin He spoke of a form of fever which he called "non malarial remittent" This is a fever of considerable severity, duration and mortality, lasting on an average six weeks, if not fatal earlier Dr Crombie never found malarial parasites in it and quinin pushed to doses of 90 gr daily was not only ineffectual but harmful The refusal to recognize such facts by other investigators he attributed to the "fallacy of finality"—the fallacy that every advance is final and that every fact in medicine must be brought into line with it because there is nothing beyond

Infectious Jaundice

Dr Sandwith, Cairo, Egypt, defined this disease as an acute infectious disease sometimes epidemic during the summer months, characterized by fever jaundice, enlarged liver and spleen, nephritis and some nervous symptoms It is not contagious In Smyrna it apparently has been endemic since 1837, and in Alexandria certainly since 1870 Professor Weil of Heidelberg has published four cases and since then several others have been recorded in Germany There have been small epidemics in England, the United States and China Men chiefly between the ages of 20 and 30 are most affected, and during the summer months No microbe has been discovered, but analogy points to the fact that it is insect borne The symptoms may be divided into three stages 1, primary fever, lasting from three to five days, 2, jaundice of from seven to nine days' duration, 3, secondary fever, for from seven to nine days After an incubation period of one or two days there is usually a sudden onset with a distinct rigor, the temperature rising to between 102 and 104 degrees, with general malaise and vomiting About the third or fourth day the jaundice begins with enlargement and tenderness of the liver, enlargement of the spleen and albuminuria, after which the fever usually subsides The jaundice and other symptoms then gradually disappear but in about three fourths of the cases there is a secondary attack of fever and convalescence is always slow The nervous symptoms are headache, giddiness and sleeplessness In bad cases there are somnolence, prostration, hiccough, lividity, dry brown tongue and muscular twitchings Muscular pains, especially at the nape of the neck and in the calves, are intense during the first stage and are increased by pressure, forming a useful diagnostic sign There is usually epigastric pain, which can be traced to the liver Constipation is the rule, but in severe cases there may be diarrhea During the jaundice the stools are clay colored Hemorrhages from the mucous membranes, especially epistaxis, may occur The urine contains albumin and bile The mortality in Alexandria is 32 per cent Postmortem fatty degeneration of the liver and petechiæ on the serous and mucous membranes are found

Leishmann-Donovan Bodies

Major W B Leishmann read a most important paper on "The Leishmann Donovan Body" Since these bodies were first brought to light many cases in which they have been observed have been recorded, and it is becoming more and more evident that the disease associated with their presence is by no means uncommon in the tropics Originally found in the spleen, they have since been found in the liver, mesenteric glands, bone marrow, kidneys, and ulcers involving the intestinal mucosa The parasites appear to be intra cellular and are found in large mononuclear cells which are probably macrophages In specimens obtained during life by splenic or hepatic puncture the parasites are usually found free in groups The principal symptoms noticed are 1, Splenic and hepatic enlargement, 2, a peculiar earthy pallor of the skin and in the late stages great emaciation and muscular atrophy, 3, prolonged irregularly remittent fever lasting frequently many months, with or without remissions, 4, hemorrhages such as epistaxis, bleeding from the gums, subcutaneous hemorrhages or purpuric eruptions, 5, transitory edema of the legs, 6, complications such as congestion of the lungs, diarrhea and dysentery have been frequently reported and occasionally cause death, 7, a marked mononuclear increase—an interesting point in view of the proved absence of malaria The disease is resistant to medication, especially to quinin, at all events in the later stages The symptoms are similar to those of kala azar, but it is too early to say whether the two diseases are identical The bodies appear to represent a stage in the life history of a flagellate organism resembling a trypanosome, if not belonging to that genus Recently Captain Rogers has announced in the *Lancet* that trypanosomes have developed in cultures of these bodies

The Museum

A most interesting feature of the meeting was the museum which contained a large number of remarkable exhibits, including radiographs and photographs illustrating diseases of the prostate and diseases and injuries of bones and joints, particularly Colles fracture and congenital dislocation of the hip Microscopic preparations showed the most recent work in the pathology of new growths A beautiful series of ophthalmologic and otologic drawings by Dr Ole Bull of Christiania was lent by the University of Cambridge A striking exhibit was a lifesize wax figure showing the injuries inflicted on the body and clothing by a lightning stroke

Senility and Infantilism

Mr Hastings Gilford illustrated some anomalies of growth recently described by him, which he terms "ateleiosis' and progeria," by four living specimens and a number of photographs These two disorders are of opposite natures Ateleiosis is a form of infantilism, while progeria is a form of senility Ateleiosis seems to be of two varieties asexual and sexual The asexual case shown was a man of 30, but had the height rounded figure, physiognomy and ossification of a boy of between 5 and 10 some parts being more backward than others The genital organs were like those of an infant He is still growing at the rate of about 5 cm a year The sexual case shown was a man of 38 whose height and proportions were those of a boy of 10, while he also possessed the flat, undeveloped face of a boy But he was sexually mature and had a family of seven, three of whom were dwarfs One of these, a boy of 12 was shown because he served as a connecting link between the two varieties, for while he was the son of a sexual ateleiosis, he himself was an instance of the asexual variety for he was cryptorchid and his genitals were infantile Progeria was represented only by photographs, all three of the subjects being dead All three presented the external and internal signs of old age One died from apparent senile decay at 17 another at 18 and the third, a less marked case at 43

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in everyday practice Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer]

Myocarditis

Stevens in *Amer Med* , discusses the diagnosis and gives the following outline of treatment of myocardial disease

GENERAL TREATMENT

'Attention to the minutiae of life is of the utmost importance Each individual must be studied as regards the state of the arteries, the character of the pulse, the digestive powers, the existence or absence of any constitutional vice and the actual condition of the heart, so far as this can be determined " Attention should be directed to proper exercise It is many times unnecessary for the patient to give up his occupation, but the sum of his exertions should in no wise fatigue the heart Fret and worry frequently have as baneful an effect on the heart as actual physical exertion Graduated exercise is indicated except in those cases where it is followed by palpitation, irregularity, pain, or pronounced dyspnea, in which cases absolute rest should be prescribed In these cases massage is useful since it gives the patient exercise without any additional strain on the heart

DIET

Avoid rich foods, bulky foods, and foods which induce flatulence Prohibit eating between meals Over eating and copious drinking at meal time must be avoided Water may be allowed between meals freely enough to secure free elimination of waste products Tea and coffee should be used very sparingly, better not at all Alcohol and tobacco should be dispensed with Avoid all excesses Avoid constipation Gouty diathesis and syphilis should receive appropriate treatment

SPECIAL TREATMENT

He recommends strychnin in doses of 1/60 gr to 1/30 gr (1 mg to 2 mg) two or three times a day If anemia is present iron and arsenic can be advantageously combined with strychnin The nitrites and iodids are of especial value when there are angioid pains, high arterial tension, and cardiac asthma The iodids are contraindicated where there is advanced arterial disease and chronic nephritis Digitalis must be used tentatively, in small doses and best when the degeneration is in its early stages It is well to guard against its constricting influence on the arterioles by combining with either nitroglycerin or sodium nitrite In some cases strophanthus is more efficacious than the digitalis and in others caffein sparteın or cactus may be tried

A Non-toxic Preparation of Iodin

Wingrave, in the *Lancet*, states that after considerable experimentation with different preparations of iodin he has found the following formula can be given for considerable periods without causing symptoms of iodism while exercising its specific effects on lymphatic enlargements

℞	Iodin	gr xl	2|65
	Acidi tannici	ʒi	4|
	Alcoholis (90 per cent)	ʒixss	38|
	Syrupi q s ad	ʒxix	76|

The iodin is dissolved in the alcohol, the tannic acid and 30 c.c of syrup are added, the solution is heated to just below the boiling point until it affords no evidence of free iodin with the starch reaction (about 20 minutes), then cooled and the remainder of the syrup is added with flavorings Each dram contains two grains of iodin Dose from one half dram to two drams in water or wine before meals according to age The iodin is in loose chemical combination with the tannic acid, and is readily given up to the tissues after absorption, and consequently there is no chance of any local intestinal or gastric irritation The author has found that children tolerate it well and it has proved of value in cases of chronic lymphadenitis associated with or independent of, enlarged tonsils and adenoids especially when the enlarged glands persist after tonsillotomy It is further indicated in those cases of enlarged faucial and pharyngeal tonsils where operation is contraindicated or objected to It has afforded gratifying results in atrophic rhinitis especially when combined with arsenic

Enuresis.

Lewis, in the *British Jour of Children s Diseases*, states that he has observed that children fed on starchy foods pass a larger amount of urine than normal, and when their starchy food is cut off this symptom disappears It is the same with victims of enuresis In most cases a rigid antidiabetic diet removes the symptoms in a few days During the cure, starchy foods may usually be allowed for breakfast without 'accidents" occurring at night As to results the author states "Without any other treatment hospital cases are relieved at once, and finally cured when fed on the ordinary hospital diet In private cases small quantities of bread or cake given at dinner or tea will cause bed wettings to recur"

Simple Diarrhea

Earp, in the *Med Council*, discusses the therapeutics of this common condition, and believes that rational curative therapy depends on four cardinal factors 1 Cleanse the alimentary canal of all offensive material and relieve pain 2 Antisepsis 3 Establishment of rational dietetic measures 4 Rest in bed

PROPHYLACTIC MEASURES

The author states that perhaps there is no disease which holds a closer relationship to errors of diet than this one If the following rules could be more carefully observed many cases of diarrhea would be averted Take food in moderate amounts, eat slowly, thoroughly masticate the food, and thus give due regard for the first process of digestion, let the mind be free from care or anxiety during the meal and rest a few minutes before and after

Care must be taken to make a proper selection of food, for the reason that decomposed material, fermented products and and impure water may produce a catarrhal condition, followed by diarrhea

TREATMENT

Cleansing the Intestinal Canal—When portions of undigested food are found in the stools it is but reasonable to suppose that others remain in the canal, giving sufficient indication for the administration of salines to free the alimentary tract of all offending material (It is also recommended to give a liberal dose of castor oil, to which a small dose of tincture of opium may be added, if much pain is present, to accomplish the same purpose as the saline) During the time of cleansing the canal it is important that very little should be given in the way of diet, and that a light diet should be continued until all symptoms have disappeared In all cases of diarrhea there is always bodily exhaustion, and likewise impairment of the digestive function Therefore, predigested foods or foods easily digested must be used with or without any of the drugs known as digestants Food should be chosen which can in the main be digested in the stomach and leave as little residue as possible Opium should only be given if necessary for the pain, and then sparingly

Of the astringent and antiseptic drugs the author recommends the sulfocarbolate of zinc, or salicylate of bismuth, and also guaiacol benzoate Under no circumstances should the bowels be locked up or permitted to be inactive any length of time

During the early stages rest in bed is of prime importance

Dysmenorrhea

Hammond, in *Amer Med*, states that the action of gelsemium in the treatment of dysmenorrhea in patients in which repeated careful examination of the pelvic organs fail to show any abnormalities or pathologic lesions, has been very satisfactory Ten drops of the tincture should be taken three times daily, begun each month seven to ten days previous to the beginning of the flow In a large proportion of cases this plan of treatment will afford absolute and marked relief

Infantile Convulsions

Merck's Archives recommends the following

℞	Potassii bromidi			
	Sodii bromidi			
	Ammonii bromidi			
	Calcii bromidi, āā	gr xv	1	
	Tr belladonnæ	m vi		3
	Syrupi aurantii floris q s ad	℥iii	90	

M Sig One to four teaspoonfuls, according to age, every two hours

If indigestible food has been taken give an emetic and a purgative A hot bath is a valuable adjuvant

Chorea

Chapman, in the *Brooklyn Med Jour*, concludes there is but one drug which has met with any success in the treatment of this disease, and that is arsenic Of the preparations of this drug Fowler's solution has given the most universal satisfaction Some cases tolerate Pearson's or Donovan's solution better Fowler's solution is best administered, beginning with small doses and gradually increasing up to the point of tolerance Some observers say up to the full physiologic effect, but the author considers this not only unnecessary but believes that the damage done to the digestive organs is certainly detrimental to the patient's general condition, which is a point that should receive our first attention He also discountenances the use of the drug hypodermically, and believes the pain and annoyance from the injection greater than the good accomplished

It is best to give Fowler's solution well diluted to prevent gastric irritation and likewise to increase the amount of liquids ingested The increased fluids prevent the extreme concentration of the urine and lessens the irritation of the kidneys Medicinal diuretics are seldom necessary, and when indicated small doses of acetate of potash may be dissolved in milk and administered without the patient's knowledge

The anemia is best treated by some preparation of iron given in small doses and well diluted The author prefers the citrate of iron and quinin dissolved in sherry wine If the digestion is good and the stomach will tolerate it, the syrup of the iodid of iron with the compound syrup of the hypophosphates makes an excellent combination

For insomnia and much restlessness he recommends the use of chloral hydrate This drug is well borne by children, and from five to ten grains in a cup of hot milk usually induces a good night's sleep

Coexisting disorders, such as malaria, rheumatism, etc, should receive appropriate treatment Quinin and the salicylates are well borne by choreic patients Any source of reflex irritation, such as adenoids, phimosis, etc, may receive palliative treatment, but surgical procedures should be avoided until the choreic symptoms have subsided

The following is recommended for chorea in rheumatic patients

℞	Sodii salicylatis	ʒii	8
	Potass iodidi	ʒi	4
	Pepsini (scale)	ʒii	8
	Syrupi sarsaparillæ comp	℥i	30
	Aquæ dest q s ad	℥iii	90

M Sig Teaspoonful in water three times a day

Olive Oil in Affections of the Stomach.

It is to be noted that olive oil is occupying a more useful and frequent place in practical therapeutics and we have read with interest the abstract of Cohnheim's article in the *Zeitschrift f klin Med*, in which he tells of another use of this drug and claims excellent results "Cases of gastric dilatation which are due not to organic obstruction, but to pyloric spasm secondary to an ulcer, fissure, or erosion, may be cured or greatly improved by the introduction of large quantities of olive oil through the stomach tube About 3½ to 5¼ ounces (100 to 150 c c) of warm oil are introduced when the stomach is empty In organic stenosis, and at first in spastic cases, previous irrigation of the stomach is required If, nevertheless, pain recurs later in the day, another 50 c c of oil should be given before bed time"

MODE OF ACTION

The oil acts mechanically as a lubricant, so that even solids glide through the altered pylorus Even in extreme pyloric stenosis oil enters the duodenum and is absorbed. It not only acts locally by relieving the pain and spasm, but improves the general condition

INDICATIONS

The following conditions have been improved by the use of the oil Organic pyloric stenosis, with secondary gastrectasis, cases of incomplete pyloric and duodenal stenosis, which are characterized by continuous hypersecretion, and the occurrence of pyloric spasm several hours after meals are also cured or improved In carcinomatous stenosis the oil prevents or relieves pyloric spasm In early cases, oil may prevent the occurrence of secondary gastric dilatation Or it may be given after the disappearance of the symptoms to prevent relapses The treatment should be continued for several weeks Cases of pyloric ulcer, with or without hyperchlorhydria, and with colic like pain occurring from 1 to 4 hours after food, are cured by olive oil or almond oil emulsion, if there are no complications, such as perigastritis

METHOD OF ADMINISTRATION

The oil or emulsion may be given by the tube or drunk a half to one hour before food, the doses are a wineglassful before breakfast, and two tablespoonfuls at mid day, and in the evening The almond oil emulsion should be freshly prepared by rubbing up a tablespoonful of sweet almonds in a mortar, pouring a cup full of boiling water over the powder, and passing the mixture through a fine sieve Sufficient water is added to make about eight ounces of emulsion, which is sweetened and drunk warm about one half hour before meals The diet should be regulated and all vegetables given as purées

Medicolegal.

Evidence of a Hope of Recovery—The Supreme Court of Louisiana holds, in the homicide case of State vs Gianfala, that, though the wounded man said he thought he was going to die, yet, if he asked the opinion of a physician, and, on his advice started on a journey to a distant city to have himself operated on, as being his one chance of recovery, his statements would not be admitted as dying declarations, it not appearing that he was not without some slight hope of recovery

Right of Physician to Enter Premises to Treat Lodger—The Supreme Court of Iowa says, in the case of Watson vs Dilts, that it has no doubt that a boarder and lodger may have an implied license to have a physician enter on the premises in case of illness so that if one went to the house for the sole purpose of treating such boarder and lodger in a strictly professional capacity he ought not to be held a trespasser But an implied license to enter the premises of another contemplates an entry only in the usual way, and at a reasonable time

Use of Sidewalks by Lame and Aged—Care Required.—The Supreme Court of Michigan says, in the personal injury case of Harden vs City of Jackson, that there is no doubt that the legislature authorized sidewalks for the use of the lame and aged as well as for the able bodied and young, but we know that the former classes should, and usually do, use greater care than the latter find necessary A man walking on crutches knows the common method of building sidewalks He knows that edges of the boards decay and knots drop out, and instinctively he learns to avoid putting his crutches in holes or cracks The court thinks it is not negligence for a city to use its plank walks, although they have cracks and knot holes through which a cane or crutch would go, acting on the expectation that the traveler must know that they are practically unavoidable, and are common to all sidewalks, long before they are sufficiently worn to justify pulling them up and building anew The city has a right, in the maintenance of its walks to expect a reasonable degree of care from all persons, and, when its walks are safe for the ordinarily prudent use, there is no negligence. If there were no walks the pedestrian might still fall, and the crutches of the infirm go down in holes made by animals, or in soft places An accident from such a cause would be a casualty So, too, there may be casualties on walks The cities are not insurers of those who walk on sidewalks, and, even though injured without negligence on their part, the same is no more than a casualty, if the walk is as good as such person has a right to expect

Drunkenness and Delirium Tremens as Defense to Crime.—The Supreme Court of Alabama says, in Parrish vs State, that while delirium tremens of itself is not necessarily a complete defense, or does not wholly excuse the person who commits a crime while in that condition, yet it may palliate or extenuate the crime and punishment, if the disease, drunkenness, or delirium tremens has gone to such an extent as to deprive the person of the capacity to have entertained the intent necessary to constitute murder Hence voluntary drunkenness, though not carried to the extent of delirium tremens, may palliate a crime, if a necessary element of the crime is specific intent In order to constitute murder in the first degree, willfulness, premeditation, and deliberation must concur with malice, and if drunkenness or delirium tremens has gone to such an extent as to paralyze the mental faculties, and to render the accused incapable of forming a design, which is a necessary ingredient of the crime, it would be a pertinent inquiry for the jury in determining the degree of the homicide and of the punishment to be inflicted And there being some evidence that the accused in this case was suffering from delirium tremens at the time, he had a right to have the jury pass on its credibility and sufficiency, and as to whether it was sufficient to prevent his being capable of forming an intent and of entertaining the necessary malice or intent to constitute murder Furthermore, on the tendencies of the evidence in this case, it could not be affirmed, as a matter of law, that delirium tremens, even if induced by voluntary drunkenness, would not support the accused's plea of not guilty by reason of insanity A person suffering under or afflicted with delirium tremens, for the time being, may be as absolutely insane as an idiot or a maniac

4 *The Value of Non operative Local Treatment in Gynecology Willis E Ford
5 The Modern Treatment of Pulmonary Tuberculosis Frank Warner
6 Plea for a More Just Judgment of Narcotic Drug Users George E Pettey
7 Open Oral Questions Wm S Lederer
8 Meteorism in Pneumonia, Its Prognostic Importance Heliodor Schiller

1 **Laceration of the Cervix Uteri.**—Baldy protests against the tendency among obstetricians to repair lacerations of the cervix primarily The objections are enormously swollen lips, so that a proper adjustment of the surfaces is difficult, and the subsequent shrinkage of the tissue under the sutures, which is of such an extent as to be uncontrollable both for purposes of apposition and for the prevention of the invasion of infection between the lacerated surfaces The effect of an operation on the morale of the patient at such a trying period is by no means the least of the objections The treatment for recent lacerations of the cervix, says the author, remains rigid local cleanliness, except when there is a sufficient hemorrhage to demand a ligature When non infection can be insured, and when the torn lips are not unnecessarily disturbed by the careless use of the nozzle of the syringe, spontaneous healing of these lacerations may be expected to a greater or less degree and what remains when nature is through with her work will be of a healthy character will give no future trouble and will need no surgical interference Stop the active discharges from the uterus keep the eroded surfaces free from their own discharges and they will soon disappear Baldy does not concur in the belief that lacerations of the cervix produce carcinoma In twenty years' work he has not seen a single case of cancer develop in a laceration of the cervix which he refused to repair Many arguments are brought forward in Baldy's article bearing on the latter proposition, but are too numerous to be abstracted

3 **Cervical Ribs in Man**—Eisendrath records a case of cervical rib discovered accidentally in a woman, aged 56, who consulted him with reference to a tumor of the breast Thirty

four cases of cervical rib are recorded in the literature The chief clinical interest of this condition is the relation of the rib to the brachial plexus and to the subclavian vessels In some cases it may give rise to a pulsating tumor just above the clavicle and be diagnosed as an aneurism In others the compression of the artery causes thrombosis of the distal portion, with resulting discoloration, coldness or even gangrene of the fingers Symptoms of pressure on the brachial plexus vary from numbness and tingling in the arm, to severe pains down the arms or in the fingers alone In some cases electric treatment or elevation of the arm gives relief In others resection of the cervical rib is necessary

18 *The Uses of X-ray in Medicine and Surgery Russell H Boggs

9 **Technical Errors in the Use of Rubber Gloves**—Collins says that often it is possible during major operations to see gross errors of technic in the manner of using gloves, errors not so much of carelessness, but of lack of instruction and thought on the subject The manner of putting on the glove is often faulty in that it counteracts the very purpose for which the glove is worn, that of covering up an unsterile object—the hand—with one that is sterile, the glove The best and most pleasant use of gloves comes from putting them on dry with sterile starch or lycopodium as a lubricant Collins prepares his gloves in the following way A wide mouthed bottle, filled with pulverized starch and provided with a piece of gauze tied over the mouth in a single layer, is sterilized in a live steam sterilizer At the same time several towels are sterilized by live steam in the usual manner The gloves are then turned wrong side out, placed in a wire cage and submerged in clean water in the ordinary instrument boiler Care should be taken that all of the glove is filled with water and the air driven out Two pair of long dressing forceps or sponge holders should be put into the boiler with the gloves The gloves are allowed to boil for from five to ten minutes, when they are taken from the cage and allowed to drain hastily With the sterile forceps the gloves are placed on one of the sterile towels, spread out flat, and another sterile towel laid over them If all the free water has been allowed to drain from the gloves, a little stroking and patting of the upper towel will thoroughly dry the outer surface (really the inside, for the gloves were turned wrong side out) in a few minutes The upper towel is then turned back and the gloves, both back and palm, thoroughly dusted with the sterile starch from the bottle With one pair of forceps the edge of the wristband is lifted and the other pair of forceps introduced into the glove until the blades grasp the web between the middle and ring fingers, by drawing on the interior pair of forceps and turning the cuff over with the other pair, it takes *but a moment to reverse the palm* or hand portion of the glove To reverse the fingers, grasp two diametrically opposed points of the edge of the wristband with the two pair of forceps, and twirl the glove two or three times about its transverse axis, this closes the orifice of the glove and imprisons some air in the palm Lay the glove on a sterile towel, press on the balloon part of the glove with another sterile towel, and the compressed air causes the fingers to be everted with a rush Dry the outer surfaces with a sterile towel Place the *gloves in a sterile towel* with a piece of sterile gauze between the gloves and on top Fold and pin the towel They can be kept several weeks without deterioration To put on the gloves for use cleanse the hands and dry them on a sterile towel, open the package of gloves, with the gauze pick up a glove and thrust a hand into it The gloved hand picks up the second glove with the piece of gauze and the other hand is clad The pieces of gauze *prevent contact* of any part of the skin with the outer surface of the glove If an adjusting of the finger tips is necessary this is not done until both hands have been clothed This method insures absolute sterility of the gloves, inasmuch as they have not come in contact with any object that was not sterilized

15 **Bacteriology of Panophthalmitis**—Johnston confirms the findings of previous investigators that Fraenkel's pneumococcus is the most frequent cause of panophthalmitis While in some cases a mixed infection of pneumococcus and staphylococcus or streptococcus has been found, the pneumococcus is probably the essential etiologic factor

18 **The X-Ray in Medicine and Surgery**—Boggs classifies the cases which are amenable to *x* ray therapy under four heads 1 *Those cases which respond readily* and, as a rule, do not need surgical interference, such as lupus, epithelioma of the face, acne, eczema and tuberculous glands 2 Those which should be treated for a short time, the mass removed and then continue *x* ray treatment to prevent recurrence, namely, carcinoma 3 Those cases of carcinoma which are considered inoperable should be treated to prolong the patient's life and make him more comfortable 4 Many cases of tuberculosis in the initial stage respond to *x* ray treatment But here the *x* ray should only be considered a useful adjunct

25 Surgery Under Difficulties in East Africa Samuel Gurney

20 **Senile Hypertrophy of the Prostate Gland**—Horwitz studied 150 cases with the view of determining the best method of operating for the purpose of effecting a radical cure of senile hypertrophy of the prostate gland, and believes that the following conclusions are justifiable 1 A routine method is not applicable, every case is a law unto itself 2 The dangers attendant on daily catheterism are greater than those of a radical operation performed at the onset of the symptoms caused by the obstruction 3 The proper time to perform a radical operation is reached as soon as it becomes necessary to resort to daily catheterism 4 The Bottini operation is of great surgical value It is applicable to a large percentage of cases In selected cases it is the safest and best method of relieving the obstruction caused by a prostatic hypertrophy When stone in the bladder is associated with prostatic enlargement litholopaxy may be performed in conjunction with a galvanocautery prostatotomy 5 A complete prostatectomy is justifiable if performed early, before secondary complications have supervened The mortality from such operation varies between 5 and 7 per cent 6 In feeble elderly patients with long standing obstruction and secondary complication *the mortality* ranges between 15 and 18 per cent If the bladder is hopelessly disabled suprapubic drainage is the only justifiable operation 7 In 90 per cent of all cases the gland can be removed readily by means of a median perineal incision The perineal operation recommended by Bryson is *the operation of choice* 8 A suprapubic prostatectomy is safer if combined with perineal drainage 9 Partial suprapubic prostatectomy is indicated in cases where a valvelike lobe exists which interferes with urination, or where there is a partial hypertrophy of one of the lobes A complete suprapubic and perineal prostatectomy combined is wisest where there is enormous *hypertrophy of the three lobes* especially when associated with tumor formation giving rise to a stenosis of the prostatic urethra 10 Perineal prostatectomy is best suited for those cases where the enlargement of the lateral lobes has a tendency to progress toward the rectum *to obstruct the*

urethra, or to project backward into the bladder 11 Prostatectomy always is attended with more danger than the Bottini operation and convalescence is more prolonged In suitable cases the latter operation, therefore, is the one of choice

22 **Etiology and Treatment of Arteriosclerosis.**—Osborne believes that while old age, nervous strain, over eating, abuse of alcohol, etc, are *contributing* causes in the production of arteriosclerosis, the essential factor in the etiology of this condition may be traced to some error of secretion of the so called ductless glands After studying the glands that furnish secretions modifying blood tension, he throws out the hypothesis that a diminution of the thyroid secretion or an increase of the suprarenal secretion, or vice versa, may be the essential cause of *arteriosclerosis* There may be too much suprarenal secretion or too little thyroid secretion at any age but old age with its normal high arterial tension is probably due to an absence of thyroid secretion and the consequent, at least relative increase of suprarenal secretion All the other contributing factors in the production of arteriosclerosis are operative in a *similar manner* and any treatment to be successful must aim to diminish the high blood pressure This can be accomplished by thyroid extract in small doses if we believe there is evidence of diminished thyroid secretion, and it must be remembered that any small dosage of iodids will stimulate the thyroid gland to greater activity and hence the long known value of this drug in arteriosclerosis The prohibition of all drugs and agents that have a contracting influence on the blood vessels will be followed by the best result. The great value of rest especially mental must not be forgotten The moderate use of tobacco after thirty years of age may be of benefit to these hypertension cases rather than otherwise It is a narcotic to the brain which removes a certain amount of nervous tension and it is a vasodilator which in moderate amount will not weaken the heart In excessive amounts however it will precipitate a cardiac insufficiency In cases of arteriosclerosis without kidney or liver lesion in a patient of sixty years of age or more it is quite possible that small doses of alcohol especially at night may cause sufficient vasodilation to produce some bettering of symptoms but this same improvement can be obtained by nitroglycerin in small doses even as little as 1/400 of a grain three or four times a day Osborne concludes by throwing out the suggestion that it is possible that in the future one of the suprarenal glands might be removed or its artery tied in gout and *arteriosclerosis*

23 **Talma's Operation**—McBrayer reports a case of cirrhosis of the liver occurring in a male patient aged 57 years in which he did a Talma's operation the operation proving successful Prior to the operation the patient was scarcely able to walk there was marked ascites and he was very much emaciated Now he is up all the time, walks anywhere on a level and up and down stairs his jaundice has disappeared and he has gained twenty pounds in weight with *two pounds* of his normal weight. The ascites has not required paracentesis for over three months The only medical treatment he has had is 15 grains of compound jalap powder, as needed and 1/30 gr strychnin nitrate three times a day

26 A Possible Cause of High tension Pulse in Nephritis. W H Thomson
27 *Treatment of Rupture of the Posterior Urethra. Weller Van Hook.
28 Primitive Medicine. E J Kempf
29 *Alcoholism and Drug Habits Their Pathology and Treatment. K. A. Enlind

27 **Rupture of the Posterior Urethra.**—The study of the literature of injury of the posterior urethra by external violence, says Van Hook, leads to the unavoidable conclusion that primary operations should be resorted to whenever possible under a technic somewhat as follows In the lithotomy position, with the grooved staff introduced through the urethra into the perineal tissues, immediate incision is made beginning a half inch in front of the rectum and extending forward toward the scrotum an inch to an inch and a half While the skin may be divided freely, the deep tissues are only to be incised beneath the sound at a point posterior to the bulb of the urethra The bulb of the urethra may then be drawn forward by means *of a blunt hook*, and the ends of the urethra must be sought The distal portion of the urethra is found at once because the sound passes through it. If the finger be passed over the deep surfaces of the wound, smooth mucous membrane may be felt guiding the operator to the proximal end of the tube With full exposure of the wound surfaces the proximal end of the urethra may be *found* by probing In *a recent* case a large probe must be used, or even a catheter but if cicatrization has occurred a fine probe or a grooved director must be used Van Hook's method of palpation which is original with him, is as follows By palpation with the volar surface of the finger the urethra can be rolled under the pubic arch as a somewhat *flattened cylindrical* mass This mass is fixed by the fingers *against the bone*, and a *longi*tudinal incision is *made* through the middle of it The finger is then introduced into this opening and the slippery mucous membrane can be recognized without difficulty The method may be carried out without the aid of inspection, if desired This is an advantage in cases where hemostasis is difficult When defects of the urethra are great enough to prevent the ends from being approximated without *too great tension* several alternatives are open for consideration 1 The method of Ljunggren, which can not, however be recommended as a routine method It makes too great demands on the regenerative power of the urethral tissues increases the period of healing and probably heightens the danger of infection 2 The parts of the urethra may be loosened from their bed 3 The method of Ekehorn an autoplastic operation The after treatment of these cases consists in the use of urinary antiseptics the administration of large quantities of water free drainage carried out according to the views of the operator and the passage of sounds to prevent the contraction of scar tissue Van Hook believes that the use of a catheter *a demeure* is harmful rather than beneficial As a *rule, if the* bladder needs immediate drainage by a tube, it is better to leave a very large catheter or tube in the bladder to pass out of the perineal wound which is left almost without transverse suture The use of the permanent catheter in the presence of infected urine often produces a suppurative urethritis that may result in permanent damage to the canal

29 **Treatment of Alcoholism and Drug Habits**—The author's treatment consists of thorough elimination and the stimulation of the nervous system by rest fresh air, exercise and diet. Large doses of strychnin and drugs of a similar class should be avoided as they have a tendency to aggravate the nerves Medicines of nerve tissue building properties should be used in large and frequent doses In case a heart stimulant should be required liberal doses of spartein sulphate can be used with perfect safety His personal experience with the various preparations of ergot has been very unsatisfactory As a curative agent ergot is a failure as an aid in restoring the vascular system to a normal condition after the addiction has been cured ergot is of material benefit

43 The Relation Between the Ocular Muscles and Refraction S M Payne

34 **Empyema of the Frontal Sinus and Superheated Steam**—Dennis emphasizes the importance of conservative treatment in the orbital complications of empyema of the frontal sinus Steam is safe, thorough, reaching all points of the sinus With proper precautions this will leave a minimum amount of disfigurement The operation is comparatively easy to perform It is not applicable to cases of necrosis, or where the disease has extended to the brain It may be used to advantage combined with the radical operation Any apparatus can be utilized that will insure high temperature The most available would be one of the forms of steam atomizers used for throwing carbolic acid spray There should be a pipe leading into a small additional metal chamber to one side of the atomizer, under which a second alcohol lamp is placed, so that the steam may be still further heated and freed from moisture From this second chamber a rather heavy rubber hose should lead to a small metal pipe A small silver eustachian catheter answers the purpose very well This should be passed through a large wooden handle so that the heat will not burn the fingers of the operator The tissues around the opening must be protected from the steam, and a paste made of powdered asbestos may be used This paste is packed around the tissue and is far superior to cold compresses The rubber pipe should be closed by pressure while taking the tip in and out of the sinus otherwise the tissues will be burned

37 **Extirpation of the Lachrymal Sac**—Todd describes his method of extirpating the lachrymal sac after its injection with paraffin as follows After the patient has been prepared properly the contents of the sac are pressed out and the sac is thoroughly and repeatedly irrigated with boric acid solution and with argyrol or another antiseptic By means of a suitable syringe paraffin, at a melting point of 110 is injected through the lower canaliculus into the sac until it is completely filled This at once hardens and the sac is outlined perfectly An incision is made in the skin over the sac in its long axis extending from one fourth of an inch below the dome down toward the lower extremity of the swelling The sac is exposed, can be seen easily, and is dissected out by means of a knife, dull instruments and scissors It should be followed well down into the duct if it is buttonholed no damage is done as the paraffin is hard and will not escape Any necrosed bone found should be curetted and drainage will take place into the nose The skin is sutured and the canaliculi destroyed by cauterization By following these directions no large vessels will be cut and the entire incision may be made below the tendo occuli If the latter is cut it should be sutured When a general anesthetic is administered the patient's head may be dropped over the end of the table as in adenoid operations to allow the hemorrhage to run out of the nostrils and prevent its entrance into the larynx If cocain is used some should be injected into the sac previous to the injection of paraffin and before making the incision the skin is anesthetized by the infiltration method in which case adrenalin also may be used

41 **Parinaud's Conjunctivitis**—The authors add one more case of this disease to those already recorded The symptoms were typical of the disease as described by Parinaud All the outgrowths were excised and ichthyol ointment was applied externally to the swollen glands and liquor potassi arsenitis minims 8, was administered internally three times a day After three weeks the process began to retrograde, the vegetations ceased forming the lid returned to nearly normal size and the glands subsided without showing fluctuation Three months after the patient was first seen the eye was practically well, there was still a slight degree of ptosis and some induration in front of the ear The scars resulting from the excisions are visible but have produced no apparent cicatricial contraction The authors made a very careful bacteriologic and histologic examination and summarize as follows The lesion consists essentially of marked cell necrosis in the subconjunctival tissue with extensive infiltration of the latter with lymphoid and phagocytic epitheloid cells This is accompanied by chronic inflammatory reaction of the deeper tissue leading to the process of organization and the production of new fibrous tissue The agent which produces the local lesion is non pyogenic, suppuration, when its does occur, probably being due to a secondary infection The infection is, in all probability, not due to any of the known micro organisms The theory of animal origin is founded on insufficient evidence The most efficient treatment consists in the early and repeated excision of the polypoid vegetations

46 **Peptic Ulcer of the Jejunum**—Robson reports a case of peptic ulcer occurring in the jejunum three years and four months after gastro enterostomy, which he treated by performing an enterectomy and Roux' operation The patient made a complete recovery

47 **Treatment of Post-Operative Vomiting by Gastric Lavage.**—White's method is based on the etiology of post operative vomiting, namely, that during anesthesia there is a condition of atony of the stomach walls, together with an exudate of chloroform or ether into the stomach, acting as an irritant, and there is formed in their presence an increased amount of toxic substances The lavage is performed immediately after the anesthetic is stopped and before the patient leaves the table The stomach tube required is one of the usual length, size and moderately stiff, one eye in the extreme end, the second half an inch from the end, and the third an inch from the end, but opposite the second No pump or bulb is necessary and the rubber funnel usually attached should be replaced by one of glass While the patient is thoroughly under the anesthetic a mouth gag separates the jaws, the head resting on the occiput The tube is inserted well back against the pharynx and gently pushed down into the esophagus until the end enters the stomach The occasional esophageal spasm is best overcome by steady gentle pressure Salt solution or sterile water is poured into the funnel, held about two feet above the patient, until a pint and a half or two pints are used, then the funnel is inverted close to a bucket on the floor at the right of the table, and at the same time the patient's head should be rotated strongly toward the right This process should be repeated once or twice or until the fluid returns clear In removing the tube from the mouth it should be pinched tightly until it is withdrawn so the fluid it may contain does not flow back into the mouth Although this method has not abolished post operative vomiting, it has lessened it to a very great extent It is essential that the patient should be well under the anesthetic at the time the tube is inserted There are three conditions in which this prophylactic treatment is indicated 1 In cases where there has been insufficient time to prepare the patient properly 2 In cases where the anesthetic lasts an hour or more 3 In cases where the patient previous to operation, has suffered with attacks of nausea and vomiting or chronic gastritis

54 **The Tuberculin Reaction.**—The authors have carried on a series of experiments having as their object the better understanding of the nature and specificity of the tuberculin reaction The subjects for inquiry which prominently suggested themselves were 1 Can the diagnostic use of tuberculin scatter the disease and produce new tuberculous foci? 2 What relation has healed or eradicated tuberculosis to the reaction? 3 Is the reaction always dependent on the presence of specific tubercle? 4 What relations have the alleged reactions from other substances to the true tuberculin reaction? Is the reaction due to enzymes like trypsin? 5 How long after infection with tuberculosis does reaction susceptibility begin? 6 What constituent of the tubercle bacillus induces reaction susceptibility in the animal? The conclusions arrived at in answer to these queries are as follows 1 In localized corneal tuberculosis of the rabbit's eye no spread of the disease could be observed after the use of tuberculin injections On the contrary, a favorable absorptive influence was noted on the diseased focus 2 Extirpation of a tuberculous focus was followed by loss of reaction susceptibility in the one rabbit where the operation was thorough 3 No signs of local reactions were found about the capsules containing tubercle bacilli, except when imperfectly sealed The temperature elevations gave no evidence of susceptibility to tuberculin resulting from the presence of bacilli in the filter capsule Hence it is evident that either the poison contained in the bacilli was not diffused through the capsules in sufficient amount to produce susceptibility in the surrounding tissue, or, if so diffused, did not remain in store in the tissues, as has been assumed to be true of tubercles containing actual living or dead bacillus In either case the presence of tubercle bacilli or their substance in the tissues appears necessary to a true tuberculin reaction Moreover, the nuclein substance of tubercle bacilli will not pass through a filter, and it is known by chemical research to be the most important poison in tubercle bacilli 4 Temperature and local reactions may occasionally result from the injection of trypsin, pepton and sodium cinnamate, but only when large doses were injected whose bulk might produce constitutional disturbance and fever Atropin produced no reaction in moderate doses Local reactions occurred seldom and, except in fatal poisoning by pepton did not bear a close resemblance to the typical tuberculin reaction It is possible that pepton contains proteid substances chemically similar to tuberculin the injection of which excites more or less reaction in the tuberculous tissue The direct action of trypsin on tuberculous abscesses failed to produce reaction and thus did not favor an enzyme theory of the tuberculin reaction 5 The temperature variations noted preclude uniform results from tuberculin reactions in the early stages of tuberculosis The reaction susceptibility is apparently distinct on the fourth and fifth days after inoculation then irregular until the thirteenth and fourteenth days after which the reactions are the rule Since ten to fifteen days are required for the full development of tubercle it is more than probable that the specific susceptibility is not fully acquired until this stage is reached 6 The tuberculin extracted bacilli used probably still retained enough active substance to produce susceptibility The fat extracted bacilli appeared to have more reacting substance than the others Neither were completely extracted so as to be free from intact well stained tubercle bacilli The nuclein substance of the bacilli was presumably more abundant in the fat extracted bacilli and may produce reaction susceptibility independently of the fat though this is only suggested by the results of the experiments

64 *Treatment of the Intestinal Fistulas by the Elastic Ligature Theodore A McGraw
65 The Influence of Breast Feeding on the Infant's Development Henry Dwight Chapin
66 Cow's Milk for Infant Feeding Augustus Caillé
67 Milk Laboratories John Lovett Morse
68 *Substitute Feeding During the First Year Thomas Morgan Rotch
69 Difficult Cases of Feeding L Emmett Holt

64 **The Elastic Ligature in Intestinal Fistulas**—McGraw considers the etiology and pathology of intestinal fistula, and in speaking of the treatment, describes his method of procedure, which obviates the necessity of a second operation in these cases The bowel is drawn out of the wound until a portion is reached that is nearly normal in appearance, and then a lateral anastomosis is made between the two limbs with an elastic ligature, the idea being to provide a passage for the bowel contents and thus *enable the false anus, which* is no longer needed, to heal After the ligature has been applied the bowel is disinfected and all that seems in condition to recover is pushed back into the peritoneal cavity That part which is mortified, and that which appears dangerously near mortification, is fastened outside of the abdomen by stitching it to the abdominal wall The immediate result of such a procedure would be the relief of the distended bowel by means of the false anus and the gradual subsidence of internal congestion When that had taken place and the ligature had cut through, it was hoped that the fistula would heal spontaneously or could be made to heal by inverting the ends of the protruding bowel—a simple operation of little danger Two cases are reported which, though fatal, were both successful in opening the passage between the afferent and efferent bowel, and in obviating the passage of feces through the false anus In both cases the false anus had begun to heal before death cut the matter short

68 **Substitute Feeding During First Year**—Rotch's article reiterates what he has said before, that infants can not be fed by rule of thumb We can only lay down the general principles governing the milk supply and subsequent modification of the milk and, finally, its adaptation to the individual infant Each infant must be studied by itself The most successful feeder of infants will be the man who is thoroughly acquainted with the many resources in our modern methods of percentage feeding, and who can appreciate the individual needs of the especial infant.

70 *Remarks on the Surgical Treatment of Obstetrical Paralysis Royal Whitman
71 The Retrograde Atrophy of the Pyramidal Tracts J Ramsey Hunt
72 Manic Depressive Insanity with the Report of a Typical Case John W Stevens
73 Microscopic Study of the Non compressed Spinal Cord in a Case of Pott's Disease Alfred Gordon

70 **Surgical Treatment of Obstetric Paralysis**—Whitman divides these cases into three classes 1 Those seen soon after birth, in which the paralysis may be combined with other, and what is often considered more serious injury, such as fracture 2 The cases brought for treatment during the latter part of the first year when it has become apparent that complete recovery is doubtful 3 The cases seen in childhood and adolescence when treatment is sought from the hope that the disabled arm may be made more useful In the first class the treatment is rest and the infant's arm should be fixed to the chest with the fingers extended Gentle massage, flexion, extension and supination of the forearm, manipulation of the fingers and the like, should be employed As soon as the local sensitiveness has subsided the same treatment should be applied at the shoulder In the second class manipulation and forced movements at each joint, with the aim of regaining the entire range of normal motion, is a first essential, combined with systematic exercise, as far as is compatible with the intelligence of the patient. It is during this period that progressive distortions occur, which in themselves prevent recovery, and it is never possible to estimate the degree of irremediable injury to the nervous apparatus until they are overcome The most important of the distortions due to obstetrical paralysis is the subluxation of the

humerus downward and backward Cases of this character are often classified as congenital rather than acquired dislocations of the shoulder The author's method of treatment of this displacement, both the congenital and the acquired, has been somewhat similar to that of the reduction of congenital dislocation of the hip Contractions are overcome by leverage of the arm, first in an elevated and an extended attitude, the aim being to force the head of the humerus forward It is then pushed upward, by lowering the arm, and finally, by adducting it forcibly while the scapula is fixed as well as may be When the displacement has been reduced other contractions are stretched The limb is then fixed, usually by adhesive plaster and the plaster bandage with the elbow behind the thorax and with the forearm, if practicable in supination across the chest This fixation is continued for weeks or months, as may be necessary After its removal more or less forcible manipulation must be carried out with the aim of preventing the tendency toward recurrence of the former attitude If the paralysis of the deltoid muscle is complete the head of the humerus must be held in its new position and in outward rotation until it becomes securely fixed or if necessary the attitude may be assured by arthrodesis If the injury to the brachial plexus has been extensive and subluxation of the humerus is not present, operative treatment may be of value in lessening the disability

80 *The Blood in Pregnancy Wm L Thompson
81 A Case of Generalized Lead Paralysis with a Review of the Cases of Lead Palsy Seen in the Hospital Henry M Thomas

75 **Breast Cancer Cured by the Roentgen Ray**—Schiff reports such a case on account of the most favorable result of the cure and also because he was enabled to study the case histologically The left thorax was invaded by a tumor with large basis and of a solid consistence, extending from the left sternal margin to the axillary cavity where it reached the glands and formed a hard bunch The surface was ulcerated and bled when touched Ten or twelve tumors of about the size of a hazelnut were located along the lower border of the larger tumor Five similar nodules were located on the back of the patient Beneath the mass of enlarged axillary glands existed a crateriform cavity having gangrenous edges and a necrotic base The supra- and infra clavicular glands were hard. The diagnosis was inoperable cancer *en cuirasse* of the left mamma with lenticular metastases of the cutis It was decided to use the Roentgen ray, and after the third sitting the pains diminished considerably and the purulent discharge was lessened Improvement continued, and four months after beginning the treatment, excepting some superficial excoriated parts, a flat scar, crossed by some enlarged capillary vessels, had taken the place of the former tumor The cutaneous metastasis had disappeared, and all the lymph glands had become soft and were diminished in size The general health of the patient was good An examination of the fragment of the lenticular nodule of the back, which was considerably diminished in size by the treatment, showed that the greater portion of it consisted of large fibers, poorly nucleated, having the appearance of cicatricial tissue Between the fibers were seen leucocytes The deeper parts of the fragment contained cancerous tissue in the shape of small bundles of cells separated by a stroma of very thin fibers A fragment of the granulated surface of the cancerous ulceration showed the normal appearance of granulation tissue with many new formed capillary vessels Another fragment excised near the preceding one showed beneath a regenerating epidermis a large layer of cutis, and in its lower layers a small nest of cancerous tissue composed of six or seven cones pressed together

80 **The Blood in Pregnancy**—Thompson conducted a series of observations concerning the blood state of pregnancy in 12 cases, all living under practically the same hygienic and dietary conditions, suffering from no constitutional disease and having no special pathological affections The observations covered a period of seven months, and each patient was examined once a month during that time Two of the cases first came under observation at the second month of pregnancy, two at the third month, four at the fourth month, three at the fifth and one at the sixth month Four of the cases were followed throughout their pregnancy and subsequent delivery, and eight are still under observation The examination in each case included (1) an enumeration of red blood corpuscles, (2) estimation of hemoglobin percentage, (3) leucocyte count, (4) differentiation of leucocytes, and (5) determination of specific gravity of the total blood content From these examinations the author draws the following conclusion 1 A moderate decrease is observed in red blood corpuscles rather early in pregnancy, remaining subnormal throughout the middle months, to rise again to normal at the termination of pregnancy—not, however, in all cases 2 A low percentage of hemoglobin constant throughout the first seven months, rapidly approaching normal as pregnancy draws to a close 3 A slight absolute leucocytosis exists in every case of pregnancy, but this does not support the theory that it is due to positive chemotaxis 4 There is no variation from the normal in the different forms of white corpuscles, the leucocytosis affecting all forms of white cells alike 5 The specific gravity is high at the onset of pregnancy diminishing by progressive steps to reach its lowest level in the middle months, rising to normal at term

84 Some Notes Concerning Domestic Remedies Formerly Used in Skin Diseases James C White
85 Reasons for Considering Dermatitis Coccidioides an Independent Disease Douglass W Montgomery and Howard Morrow
86 A Case of Multiple Myomata of the Skin W A Hardaway

82 **Peculiar Eczematoid Eruption**—Stelwagon describes cases of eruption about the region of the lips that had many of the aspects of eczema, but with such unusual features as to give it a distinctive stamp The eruption usually begins on the vermilion of the lips, and shows at first as a slight superficial eczematous irritation with scanty exfoliation, and in some cases, or at times in the same case, variable crusting There never seems to be any liquid exudation There is rarely any distinctive thickening or infiltration, some burning and heat are sometimes complained of, but seldom any troublesome itching Slight fissuring is not uncommon, especially at the angles of the mouth, and these may be painful The condition may retrogress and fluctuate, or even relative or complete recovery take place, to be followed, as a rule, sooner or later by collapse After some weeks or months the disease generally extends somewhat on to the skin proper, either more or less evenly or with a slight or pronounced segmental border Usually after some duration, or sometimes coincidently with the lip involvement the malady spreads inward to the contiguous mucous membrane, where it appears first as an ill defined pinkish discoloration which later looks somewhat thickened, of a deeper red, and with or without a superficially abraded or coated surface, sometimes slightly roughed The disease is limited usually to the lower lip In two or three instances the upper surface of the tongue also was invaded but the invasion was not characteristic of leukoplakia Usually the mucous parts are only slightly sensitive or tender except when the patient takes very hot drinks or acid fruits The neighboring cutaneous surface also becomes invaded The face lesions are rarely seen higher up than the level of the alae nasi, their most common region being just beyond these parts and near the angles of the mouth and on the chin The disease is evidently of a benign character and leaves absolutely

no trace The interest naturally centers itself in the question of diagnosis, which hovers between eczema seborrhoicum, lupus erythematosus or a disease *sui generis* The disease on the skin is rebellious and that on *the mucous membrane* seems almost irremedial The treatment of the cutaneous lesions that seems to be most useful is similar to that of eczema seborrhoicum On the vermilion of the lips occasional mild superficial cauterization with liquor potassæ and the subsequent application of a soothing ointment will have a curative influence After relief is afforded attention to the digestive tract will do much toward warding off relapses, which are the rule Beyond the maintenance of the free action of the bowels and caring for the digestive functions, little else seems to be called for or is of any distinct service in *the way* of constitutional treatment

87 **Hook-Worm Disease**—Stiles describes the species of hookworm found in man with reference to its general structure, its habitat, eggs, embryo and method of infection The classes of cases and the symptoms of the disease are discussed thoroughly, special emphasis being placed on the so called hookworm stare" and the findings in the feces The distribution and economic aspects of the disease also come in for their share of attention With reference to its prevention Stiles says that the most rational and radical method of procedure is to dispose properly of the fecal discharges, as these are directly responsible for the conveyance of the infection It is necessary, first, that state and local boards of health call attention to the necessity of building properly constructed privies, using them after they are built, and cleaning them periodically Second, the physician after seeing his patient, should inspect the hygienic conditions of the premises and instruct the family in the methods by which the disease is spread. Cotton mills and other factories should instruct their employes in the fundamental principle of hygiene which will restrict the spread of hookworm disease Men seeking employment in mines should be subjected to examination for hookworms and if found infected should be excluded from employment until they have been treated properly Boiling or filtering the drinking water and personal hygiene are also of importance but dwindle into insignificance when compared with the proper disposal of fecal matter Stiles suggests the following treatment Place the patient on a milk and soup diet for two or three days Give an aperient to clear out mucus, which so frequently covers the worm A mixture containing senna 2 oz calomel 6 gr is divided into four doses one dose to be *given every two hours beginning at noon* The following day give 31 gr of thymol at 8 a m and again at 10 a m, and magnesium or other laxative at noon Caution the patient not to take any alcoholics while the thymol is in the body If he is weak give stimulants other than alcohol Let the anthelmintic treatment rest for a week but give the patient good nourishing food and iron Repeat the treatment once a week until the parasites are all expelled

8 *The Organization of the Treatment of Syphilis in the Navy F H A Clayton
9 *Note on the Wounded in the Naval War Between Japan and Russia, 1904 S Suzuki

4 **Etiology of Mediterranean Fever**—Bassett Smith summarizes his paper as follows Mediterranean fever shows no sign of decrease at Haslar Both officers and men suffer severely, but the percentage of young officers and men in early adult age is proportionately great All ships appear to be equally affected, according to the time spent by them at Malta Harbor, the permanent harbor ships giving the most cases Men very frequently contract the fever while in Malta Hospital, while admitted for other diseases, and the nursing staff in attendance on them show a great tendency to develop the disease, but whether that is due to its endemicity or to direct infection there is no clue Most of the cases occur during May and June There is no evidence of infection being received from the shore other than through the agency of wind carried germs The organism can retain its vitality for a considerable period when desiccated, but dies in about five days in sterile fresh and sea water and urine, but remains active long in sterile milk The organism is very virulent in laboratory cultures, readily causing attacks when taken in by the mouth or through accidental inoculation The micrococcus melitensis is present in the peripheral blood in all cases during the early stages and in severe pyrexial relapses In the afebrile intervals and following cachexia it is not demonstrable In no case is it very abundant The disease may remain latent for several months, and relapses may occur for a period of two years at least, but when once completely cured it confers permanent immunity The evidence at hand suggests that in the presence of bad sanitation where the disease is endemic, infection is probably conveyed in dust by winds, mostly in the hot dry months following the rains, and that it gains access to the patient through some breach of surface, probably in the throat

8 **Treatment of Syphilis in the Navy**—Clayton says that men who have contracted syphilis should have the consequences of their misfortune impressed on them by giving them a small pamphlet of advice, and should, as far as possible, be prepared both for combating the disease and for preventing any ill effects of mercury by proper care of the teeth, etc Their attendance for observation and treatment should be made a part of routine both in ships and shore establishments, and proper records of attendance kept Such records should include the dates and nature of symptoms and treatment and any other points of value, in order that to ensure continuity, the requisite information might be sent with the patient on transfer to another ship

9 **Observations of a Japanese Naval Surgeon**—Suzuki's experience during several actions has led him to the following conclusions as regards the surgical arrangements on board warships 1 First aid dressings are of importance if applied immediately after the injury, at the site of its occurrence, instead of being applied in the surgery or hospital Ambulance parties should be stationed at various parts of the ship The practical and careful education of ambulance parties is essential to future progress in the treatment of wounds 2 The first aid packages used in the navies of different countries are folded too small, as the wounds inflicted by shell fragments are always larger than those made by small caliber rifle bullets A convenient size for the sterile absorbent cotton wool is four inches square and one quarter inch thick, covered with gauze and stitched in a few places around To this pad the middle part of a gauze bandage eight feet long and four inches wide should be stitched and kept aseptic This does away with the triangular bandage 3 The modes of carrying the wounded vary with the size and build of the ship Hand carrying is practiced in small ships In the battleships and first class cruisers, stretchers may be used if the surgeons impress on the bearers how to handle them quickly No one form of stretcher is suitable for all purposes on board ship 4 On board warships in action surgeries should be provided in more than one place, even when there is only one surgeon on board A place below water line is preferable, but every ship does not allow surgeons to do this 5 Slight protection may save serious injury to the body It is possible that in time every combatant on board warships in action will wear some kind of a protecting mask and jacket, such as the rifle proof jacket devised by the Germans some time ago It is important to remember, in regard to the disposal of wounded men, that the non firing side of a ship is more dangerous than the firing side, that is, the one exposed to the enemy, as the fragments of bursting shells are disposed in a radiating manner 6 Strict observance of aseptic surgery is essential in military as in civil surgery, but the performance of serious operations on board warships is incompatible with the good progress of cases It is advisable to transfer such cases as soon as possible to hospital ships The surgeon in chief must take care to secure the fullest efficiency in the use of hospital ships as non combatant steamers are desired to be left as far as possible behind the actual seat of war

19 A Case of Sloughing Pancreas Death from Secondary Hemorrhage W H Brown.

10 **Citrate of Soda in Infant Feeding**—Poynton attaches more importance to the peculiar nature of the fluid fed the infants as a substitute for mother's milk than to its percentage *composition* It is not always possible to obtain the proper kind of milk, nor can all babies be fed alike because of individual peculiarities For some time the author has been following a method proposed about eleven years ago by Dr A E Wright, that of mixing with each feeding citrate of soda The advantages accruing from the use of citrate of soda are 1 It renders the curd of cow's milk more easily digestible 2 It is cheap 3 It is convenient to handle, easy to control and progressive in principle 4 It allows the milk to be given in a more concentrated form and thus avoids, to some extent, the danger of underfeeding 5 There is no danger of scurvy 6 Given as a medicine it gains the confidence of the mother The indications for its use are (1) as a routine for weaning a healthy infant onto cow's milk, and (2) for correcting milk dyspepsia The drawback is a tendency to constipation, which is, however, easily controlled The limitations are 1 In rare cases of complete intolerance of cow's milk 2 In severe cases of gastroenteritis from impure milk 3 In organic disease, such as congenital hypertrophic stenosis 4 In very intractable cases which have been subjected to all sorts of different methods beforehand. As a routine method for the artificial feeding of the poor child, the best is citrate of soda in the milk, provided the milk is sound

14 **Interrupted Circulation as a Therapeutic Agent**—Ewart discusses the physiologic action of "interrupted circulation" in the treatment of rheumatoid arthritis He believes that the emptied arteries suddenly receive a ramming charge when the tourniquet is removed, and that the internal surface of the capillaries and of the lymph spaces, in which they are immersed, is submitted to sudden stimulation On the other hand, during the preceding stage of ischemia a certain amount of suction must have existed within them, not only owing to the collapse of the elastic tissues, but also from the intravascular negative pressure set up by the procedure The tendency would be for the emptied blood vessels to suck up some of the remaining tissue lymph or in cases of inflammation some of the more fluid inflammatory exudates In rheumatoid arthritis, with its special features of immobilization of the joints and of stagnation of the lymphatic circulation, both theories would fulfill direct indications, and it proves to do so in the two cases cited by the author The technic is exceedingly simple A padded armlet of soft leather, or a circular pad of lint and cotton wool of sufficient thickness to protect the nerves having been secured round the upper arm, or the thigh, a loop of India rubber tubing of suitable thickness is passed behind the limb over the pad, and the two ends of the loop are strongly put on the stretch with one hand The other hand grasps the tubes close up to the front of the lint, thus tightening the loop into a strong ligature or tourniquet The degree of arterial occlusion depends on the strength with which the two ends of the loop are pulled up, the limb having previously been drained of much venous blood by raising it and by stroking the larger veins empty The compression quickly induces blanching of the skin and numbness of the extremity, similar changes doubtless taking place through the thickness of the limb For ordinary purposes half a minute, or at most two minutes of this will suffice. The tube is then let go, and this is at once followed by a bright cutaneous flush of capillary injection and a pleasant feeling of warmth The same maneuver is repeated, say six times at intervals of a few seconds Two or more such sittings may be used daily In both the author's cases the results have been most satisfactory The synovial and lymphatic effusions have been benefited more largely than the periarticular fibrosis, and this is consistent with the views expressed as to the probable mode of action of this method In the treatment of the stiffness of joints there is a definite help in the numbness which accompanies the stage of ischemia, and which allows, within prudence, an increased amount of passive motion to be applied The method would, therefore, be specially promising in the early stages and in the exudative forms of rheumatoid arthritis, it being understood that it is merely an adjunct in our treatment, from which we can not spare any other available resource, whether local or constitutional

30 **Treatment of Pruritus.**—Trémolieres reviews the various endocutaneous hematic and nervous causes that may contribute

to induce pruritus He attributes it essentially to a pathologic condition, an exaggeration of the perpetual and reciprocal interchange of impressions between the nerve centers, the tissues, the viscera and the sensory and cutaneous terminals, a true nervous circulation, with a closed circuit In this closed circuit excitations circulate and can not escape They accumulate, and although each may be trivial in itself, yet by their accumulation they pile up a state of sensory excitability which in time manifests itself as pain or pruritus Each cell stores up in its memory the excitations that have acted on it, and this "mnemodermia," as Jacquet calls it, aids in locating of a pain or pruritus later For example, if the hands are chilled during a drive, a glass of spirits later in the day is liable to induce pruritus in the parts of the hands that had been most exposed Pruritus may be described as the exaggeration of those elementary cutaneous sensations which emanate from the sensory fibers of the great sympathetic nerve Prophylaxis of pruritus consists in avoiding nerve strain and overwork of all kinds, in studying temperance in all things, with an easily digestible diet, wearing linen or fine cotton next the skin, with exercise and cold douches or tubs, followed by frictioning, to aid in the distribution of the peripheral sensibility Removal of the cause of the pruritus may be promoted by venesection, 200 to 250 gm, repeated after a few weeks if necessary Among the symptomatic measures great relief may be obtained from tempered douches, once or twice a day, at 35 C, one to three minutes at a time, the jet interrupted, terminating with a brief, very cold douche The various modes of treating pruritus by different authorities are reviewed, but the main stress is laid on prevention by removing the cause and reducing the general nervous excitability

32 **Cirrhosis of Liver and Appendicitis.**—The influence of appendicitis on the liver is confirmed by the case described The patient was a young man who succumbed to peritonitis the fiftieth day after the first vague symptoms of appendicitis Two appendicitic abscesses had been evacuated At the necropsy the organs were found sound, with the exception of the liver, which presented a typical picture of recent portal cirrhosis There were no antecedents of alcohol, malaria or syphilis, and the connection between the appendicitis and the sclerous process in the liver seems unquestionable Letulle, Achard and Dieulafoy have observed somewhat similar cases All this testimony suggests that the plan of waiting and operating *à froid* in appendicitis may leave the liver and kidneys a prey to evils that might be avoided The intensity of the infectious process and the reactional aptitude of the subject, with his inherited predispositions, will determine whether the result is trivial and transient or entails a chronic nephritis or cirrhosis of the liver

34 **The "Curtain" Operation for Femoral Hernia**—Chaput points out that in very large femoral hernias the neck of the sac extends in front of the femoral vessels in such a way that the hernia is liable to recur through the femoral canal, either in front of the femoral vessels or inward from the femoral vein The best technic to prevent recurrence consists in pulling down, like a curtain, the internal oblique and the transversalis, as far as the pectineal spine, completing the operation by suturing the sheaths of the vessels to Poupart's ligament, both in front and inside, and also to the internal oblique He has operated on 10 patients by this "curtain" technic, and has found it highly satisfactory in every respect

41 **Isolation in Public Hospitals in Hysteria and Neurasthenia**—Déjerine is so impressed with the value of isolation and psychotherapy in the treatment of hysteric and neurasthenic women that he has adopted these measures in his general hospital practice He isolates the patient's bed in the ward by curtains around the bed, prohibiting all intercourse with the family, friends or even the nurses The visit of the physician in the morning and of the interne in the evening, and the attendance of the nurses under the strict supervision of the head nurse, are the only means of communication between the patient and the world outside her curtains The only exception is that other patients of the same category, improving or cured under this treatment, are brought to the bedside and allowed to describe the favorable results obtained in their case The course of isolation and psychotherapy lasts at least three or four weeks, but it is astonishing how complete and permanent the cure attained in this way in the public hospital These isolation cures have generally been regarded as the prerogative of the rich During the first week or so nothing is given the patient but milk, from three to five quarts a day Forty patients have been thus treated, and wonders have been accomplished in the cure of extreme emaciation, fixed ideas and the phobias of neurasthenics and of the contractures and paralyses of hysteria

42 **Improved Technic of Palpation of Abdomen**—Mayor mentions among other points that if vaselin be rubbed into the skin of the abdomen palpation is very much facilitated The organs can be examined almost as if they were stripped of the parts above

48 *Review of Recent Works on Public Health etc G Meyer (Berlin)—Sammelreferat

43 **Further Inoculation from Syphilitic Chimpanzee**—Lassar gives an illustrated description of his successful inoculation of a second chimpanzee from the first one which he inoculated with human syphilis, as mentioned in these columns at the time The course of the infection was identical in each The primary sore healed completely and the syphilitic lesions developed later on the brow, soles, arm and hand These successful results suggest the possibility of obtaining an effectual curative serum from these animals [The Paris dailies, by the way, relate that two apes which are being made the subjects of experiments in this line at the Pasteur Institute, were recently taken out for a walk by an attendant One of them broke away and attacked an infant in a passing baby carriage, scratching it severely The infant was taken into the institute, and the parents reassured with the statement that the ape had not yet been inoculated with syphilis—Ed] Both of Lassar's apes succumbed later, one to genuine pneumonia, the other to acute miliary tuberculosis

44 **Case of Transient Diabetes**—Mann remarks that the transition of diabetes insipidus into diabetes mellitus is a rare occurrence—he knows of only a single instance, reported by Senator in 1897 He describes an additional case, which was under constant observation all the time Diabetes insipidus developed under his eyes, and this in turn changed into genuine diabetes mellitus, accompanied by intense acidosis This severe affection lasted only 16 days, and then disappeared as suddenly as it had come on, the acidosis vanishing before the sugar in the urine Such an acute course of severe, typical diabetes passing into at least temporary, complete recovery, is a hitherto unknown phenomenon The few cases of transient diabetes on record always lasted at least six weeks, and were consecutive to trauma or infectious diseases, in youthful subjects The patient in the case described was a man of 45, who entered the hospital on account of cholelithiasis with a possibility of cancer in the stomach Diabetes insipidus developed under expectant treatment for a month, and this became transformed into diabetes mellitus, but by the end of the second month the patient was free from any symptoms of either Two or three months later he succumbed to sudden hematemesis, and the necropsy revealed a gangrenous carcinoma in the lesser curvature, adherent to the pancreas The liver and brain were apparently normal, and the pancreas was macroscopically intact If the pancreas had been microscopically cancerous, diabetes due to this source would have persisted without change to the end The recovery noted speaks against any anatomic connection between the cancer and the diabetes

47 **Importance of Intestinal Gases for Pressure in Pleura**—Aron summarizes his experiments in the statement that the pressure in the pleura varies when the intestinal gases are sup

pressed He experimented on *animals in* the pneumatic chamber

48 **Recent Works on Public Health, Vital Statistics, Etc**—Meyer reviews a host of recent works inaccessible to physicians in general and yet repaying study Among the points brought out we note that the morbidity in the Prussian army dropped from 908 3 per thousand in 1890 to 682 5 in 1808 The mortality has fallen from 4 1 per thousand in 1885 to 2 2 in 1898 The proportion of venereal diseases has dropped by 10 per thousand during the last five years, although the army numbered 10,218 more men In the German army, *1898, the proportion* was 19 9, in the French army, 37 2, Austrian, 61 5, Italian, 96, and English, 132 7 There has been a decrease in all the armies since 1881 The mortality from cancer in Saxony increased from 58 to 96 per thousand inhabitants between 1873 and 1899, although the total mortality during this period has fallen from 28 7 to 23 3, and that of tuberculosis from 2 29 to 1 98 The collective cancer inquiry of October 15, *1900* showed 160 male cancer subjects and 269 female to every million inhabitants in the German Empire Behla has recently published "Die Carcinom Litteratur," in which the titles of 5,500 works on this subject *are* given, classified by the organs affected He urges that greater attention should be paid to cancer in plants and animals His book is the outcome of years of painstaking collecting

50A **Ephemeral Traumatic Glycosuria.**—Kausch noted this phenomenon in 11 cases of recent trauma, fracture or contusion He ascribes it to the psychic excitement induced by the injury

50B **Narcosis in Diabetics.**—Chloroform should be systematically avoided for diabetics, ether is the anesthetic for them, preferably operating during the first whiffs Chloroform induces more acetonuria than ether The amount of the narcotic and the duration of the narcosis should be reduced to the minimum Inhalation narcosis should always be undertaken early in the morning, and the diabetic should always be prepared for every operation with sodium bicarbonate until the urine gives an alkaline reaction The narcosis should be restricted to a sugar free period, if possible, but it should not coincide with the disappearance of the sugar or follow it too closely If coma impends or has already developed, push the bicarbonate per os, per anum, subcutaneous *and* intravenous Gluconic acid (carbohydrate acids) should also be given a trial It is consumed by the organism, does not burden the carbohydrate metabolism and reduces the acetonuria

50C **Lumbar Anesthesia.**—Klapp announces that an oily vehicle retards the absorption of cocain Dogs can be injected subcutaneously with a fatal dose of cocain in an oil medium without any symptoms of intoxication. It is also possible to induce complete general anesthesia in a dog by injection through lumbar puncture of cocain, in a concentrated solution of gelatin, without any signs of toxic *action* His experiments have demonstrated that the absorbing power of the dura is tremendous Intradural absorption occurs in the first hour, while the subcutaneous requires five hours Adrenalin retards dural absorption, but not as much as it retards the subcutaneous Lumbar anesthesia with cocain in a mucilaginous vehicle is a peculiarly convenient and effectual method of inducing general anesthesia in animals for surgical purposes Dogs thus treated allow, without a sound, operations on the most varied parts of their body The technic is particularly adapted for veterinary practice The conditions are different in man Man has more cerebrospinal fluid and does not tolerate cocain as well as the dog The necessary fractioned sterilization of the gelatin might also interfere with its efficacy in man

50D **To Enhance Resisting Powers of Peritoneum.**—Mikulicz reduces the danger of an *inflammatory* reaction in the peritoneum during abdominal operations by artificially enhancing its resisting forces As a specific immunization is out of the question, owing to the multiplicity of the causal *agents,* he accomplishes his aim by inducing an artificial hyperleucocytosis Nucleic acid was found the most energetic agent in this respect of all the substances tested Twenty to forty times *the other*wise fatal dose of coli infection is tolerated by the guinea pig's peritoneum without reaction when the nucleic acid is injected seven hours before the operation The measure has been tried on man in 34 instances It seems *as harmless in the clinic as in* experimental tests, and it frequently induced a hyperleucocytosis up to 25,800 The maximum is reached in man about twelve hours after the injection All the patients passed *through the dangerous* first week without any peritoneal complications The operations had included 7 resections of the stomach, 13 gastroenterostomies and other severe abdominal operations One patient succumbed *to pneumonia* three weeks later, and one in a month to a pre existing complication. The general course of the recovery seemed smoother than usually observed. He injects 50 c c. of a 2 per cent solution of neutralized yeast, nucleic acid injected subcutaneously in the chest wall He advocates copious rinsing of the abdominal cavity with warm physiologic salt solution, as this has also a tendency *to* elicit hyperleucocy*tosis* in the *peritoneum* beside its other advantages

50E **Thrombosis in Mesenteric Vessels During Operations.**—Payr noticed that the *omentum appeared inflamed in 7 cases* when the abdomen was opened. During the course of the operation he witnessed the development of thrombosis in the adjacent veins of the omentum or intestine Nothing in the operation had inflicted any mechanical injury on these veins, as this was especially guarded against Inflammatory processes evidently afford a predisposition In case of infectious embolism, symptoms of intoxication predominate and the prognosis is serious, the hemorrhages appear early In non-infectious embolism the hemorrhages do not appear until the seventh to the eighth day, and may be arrested by therapeutic measures or spontaneously In case of extensive thrombosis of the mesenteric veins, the connected intestine should be resected, as also the omentum in case of thrombosis of any of its veins It *must* be done very cautiously without traction or injury of the sound parts Further data should be collected in regard to venous thrombosis in the abdominal organs, and it should be studied from a broader standpoint

50F **Horizontal Abdominal Posture After Laparotomies.**—Küster's experiments with colored fluids on cadavers showed that all the fluid injected into the abdominal cavity drained away when lying flat on the belly In 6 cases of septic peritonitis he had the patients assume this position after the laparotomy, and here extols its advantages A bolster under the chest allows the arms to be moved

50G **Treatment of Hernia by Injections of Alcohol.**—Brodnitz has treated 73 cases of hernia by injecting .5 to 5 gm of alcohol around the inguinal canal, repeating the injection every second or third day until four to ten have been made The tissues around the hernial opening swell and harden under the influence of the alcohol The injections are continued once a week for two or three *months* by which time there is a cicatricial induration which opposes an effectual barrier to the tendency to hernia The results are most beneficial in the incipient cases and in children, but the method is applicable for all cases in which an operation is contraindicated or refused.

50H **Treatment of Excessively Large Hernia.**—Madelung applies the term "übergrosse Hernien" to those in which reduction is impossible, even *by an operation* He treats such cases by resection of the redundant mass of intestines, or by making a fistula in the afferent portion of the intestine It acts like a safety valve, warding off constipation and its consequences Helferich has observed 2 deaths following sudden reposition of an excessively large hernia Kausch resects the omentum in such cases, but has never resected the intestine for this cause alone

50i **Splanchnotripsy**—Lanz has been applying Doyen's angiotribe to intestinal surgery for "splanchnotripsy," and comments here on its many advantages It is particularly valuable in appendicectomy He has not had a single death or fistula in 15 early and 405 cold operations for appendicitis since he has been using this splanchnotribe Exclusion of the intestine is rendered easier by it, as also implantation of the ureter, making an artificial anus for a safety valve, etc He found that the lumen of the intestine became permeable again in time, although the crushed strip was 1 5 cm wide, and had been re enforced by a ligature

50j **Early Operation for Kidney Tuberculosis**—Kümmell emphasizes that the best way of curing tuberculosis of the bladder is by removing the kidney responsible for the infection The bladder should never be operated on for local tuberculosis, but the kidney above should be removed as soon as possible In 260 operations on the kidney, tuberculosis was found in 48, all but 15 of the subjects being women A primary focus elsewhere in the body was certain or probable in every case The kidney became infected by way of the blood or lymph, and the bladder was infected in turn from the kidney Tubercle bacilli were found in the urine in all of the 6 cases reported in detail, although considerable efforts were required to detect them The prognosis of tuberculosis of the kidney is favorable on condition of complete removal of the organ He obliterates the ureter its entire length by inserting a galvanocautery in the shape of a sound, which can be heated for 10 cm from its tip It is inserted cold in the ureter from the nephrectomy wound to the bladder, and the current turned on This insures the complete obliteration of its entire lumen Of the 32 nephrectomized, cured subjects followed to date, the interval since the operation is fifteen to three years in all but 5, and two years in the latter Eight patients have been nephrectomized during the last year Krönlein of Zurich reports 24 still living out of 34 tuberculous nephrectomized patients None of the deaths was due to insufficiency of the remaining kidney The interval since the operation has ranged from one to fourteen years Küster remarked that the finding of tubercle bacilli is not an infallible sign of urogenital tuberculosis He has recently encountered a case of this kind In the course of a convulsion there was hemorrhage from the urinary organs, and tubercle bacilli were detected in the urine, and yet both kidneys were completely free from tuberculosis—as shown by excised portions—and there was only interstitial atrophy He advocates exposure of both kidneys to decide in dubious cases Rosenstein emphasized the value of palpation of the ureters through vagina and rectum as an aid in the diagnosis The ureters are involved very early in a tuberculous affection of the kidneys, and the positive results of palpation of the ureters may dispense with their catheterization Steinthal's experience has been that tuberculosis of the kidney is very rarely primary, and that the other kidney is liable to become affected in time In one case there was an interval of five years of health after nephrectomy, but then the remaining kidney presented the same symptoms He believes in operating only in case of severe, destructive processes, but Kümmel insists on the progressive nature of the affection Kapsammer stated that exposure of the kidney alone does not always suffice In one instance he found a cavity in the upper pole on slitting the organ when nothing in the aspect of the kidney had indicated its existence

50k **Venous Hyperemia**—Henle's technic has already been described in these columns A rubber tube is wound around the limb and held with a clamp It is then pumped full of air, which insures constriction with accurate dosage of the pressure by connecting the tube with a manometer This technic is particularly valuable for constriction preliminary to local anesthesia

51 **Sweeping Out the Choledochus.**—The German word which Kehr employs, "Fege," is the term applied to sweeping out a chimney He now makes a practice of cleaning out the common bile duct by pulling a strip of gauze through it, thus sweeping out all concrements that may be lurking in it He has found that the gauze always brings numerous small stones or scraps to view, whose existence it was impossible to determine by any other means In one case he repeated the process five times before all the scraps of concrements were completely removed In this case, as in 2 other similar ones, he performed ectomy, cysticotomy, incision of the supraduodenal portion of the bile duct, duodenotomy, papillotomy, "choledochus-fege," choledochus drainage and hepaticus drainage The length of such an operation varies from an hour to an hour and a half Recovery was uneventful in each instance, as also in his 6 cases of drainage of the hepatic duct Since last April he has performed 25 gallstone operations, and found stones in the common bile duct in 9 of them After removal of the gall bladder he slits the cystic and common bile duct to the duodenum and removes the stones from the retroduodenal part of the duct, pushing them up and picking them out with forceps Exposure of this part of the duct never caused any appreciable hemorrhage In 2 cases he mobilized the duodenum according to Kocher's technic and found it a valuable aid In 3 cases he was obliged to incise the duodenum The papilla was seized with Konig forceps, incised and the stone removed He then inserted a forceps of the kind Kocher uses for drawing down and out a hernial sac, inserting it from the duodenum into the papilla, and pushing it through the bile duct in the direction toward the liver, until it appeared to view again in the incision in the supraduodenal portion of the duct The blades of the forceps were then slightly opened and a narrow strip of moist gauze was placed between the blades and drawn down backward with the forceps into the duodenum, thus sweeping out the bile duct as a chimney is swept He thus advocates for suitable cases transduodenal choledochotomy, with consecutive "choledochus fege" and careful suture of the duodenum, reinforcing the suture with omentum, as a thorough and certain operation which has afforded excellent results in his hands, as he describes in detail

52 **Prophylactic Hemostasis in Trephining**—Heidenhain's method of preliminary hemostasis—described in THE JOURNAL, xlii, page 930, abstract 71—has been modified by von Hacker, who takes merely a single row of the overlapping stitches on the outer side of the incision for the flap, instead of on both sides This leaves the flap intact, while the hemostasis is ample for the purpose of trephining He describes a case to show the advantages of this technic Of course, this percutaneous running stitching with a single thread is adapted for the cases alone in which no large vessels are involved in the base of the flap

53 **Open Treatment After Transplantation**—Brüning waxes enthusiastic over the fine results observed when the wound is left open to the air after application of Thiersch flaps Healing proceeds very rapidly, both on fresh and granulating wounds He has found this technic peculiarly valuable for operation under local anesthesia, such as is generally used for Thiersch grafting When possible, he has the patient remain lying quietly on the table for several hours before he is moved, to allow the grafts to adhere to the surface beneath before he stirs When the subject is in bed he applies a wire frame over the part to protect it from contact with the bedding Serum exudes between the grafts and sometimes forms tiny blisters under them The grafts are usually firmly adherent in six to eight hours, and he lightly presses out the serum from the blisters, using a gauze pad for the purpose, without fear of dislodging the grafts A dressing can be applied during the night if there is danger of rubbing the parts during sleep, but otherwise he prefers the open treatment for both day and night The grafts all healed in place by the eighth day, at latest, the superfluous parts along the edges drying up and dropping off None of the grafts shriveled afterward There is not the slightest tendency to maceration with this open treatment, the blood coagulates and helps to hold the grafts, and the danger of displacing them by the dressings is entirely obviated

54 Diminished Responsibility—Two recent sensational cases in Germany, the Dippold and the Prince Arenberg cases, have focused public attention on the questions of diminished responsibility and the socially dangerous insane Several important works have been published on the subject, and the tenth conference of the German branch of the international association for the study of criminology adopted a set of resolutions at the Stuttgart meeting in May The lawyers' congress, to convene in September, has also appointed these questions for discussion. Aschaffenburg reviews the recent works and discusses the views advanced, giving the Stuttgart resolutions, which are as follows 1 Criminals not fully responsible for their acts should receive a milder sentence Appropriate measures to protect society should be imposed in the case of those acquitted on account of absolute lack of a sense of responsibility, as also for those whose sentence is milder on account of diminished responsibility Similar protecting measures should be imposed on persons with diminished or lacking sense of responsibility, although they have not yet committed a crime These protecting measures should be imposed by a special process similar to the process of the guardianship of minors 2. The president of the international association is commissioned to request that a law to this effect be enacted for the empire 3 Mentally deficient prisoners should be placed under the special supervision of the physician. The physician should have the deciding voice in regard to these prisoners' disciplinary and other treatment, and also in regard to appealing for their release from the full execution of their sentence

56 Retrogression of Carcinoma on Mice Under Radium Rays—Apolant has previously described his cancer research on mice (See page 1111 of vol xlii) He here illustrates the microscopic findings during retrogression of the carcinomas under the influence of radium rays The carcinoma cells vanish, and there is a proliferation of connective tissue The radium rays evidently have a specific destructive action on the carcinoma cells, supplemented by the inducing of a specific absorption of the dying carcinoma cells under the influence of the rays This specific action is shown peculiarly vividly in the case of carcinomata on mice, as the dying cells are not absorbed nor cast off without the radium exposures, the animals otherwise carrying them around as dead ballast so long as they live This necrotic mass is generally cast off under intensive radium treatment powerful enough to induce ulceration and transform the cancer into an open ulcer, after which the cancer cells are absorbed and the lesion heals The rays have to be applied so vigorously to accomplish this result that some of the animals succumbed The lack of penetrating power imposes a limit on the efficacy of radium treatment which renders it dubious whether as a therapeutic measure it has much of a future

57 Successful Treatment of Alopecia Areata with Iron Light—Kromayer of Berlin does not hesitate to proclaim that phototherapy with the iron lamp is by far the most effectual means at our command for treating alopecia areata We can confidently count on a cure with it, even in those cases in which all other measures have totally failed. His technic is simple, convenient and does not require much time The results observed confirm the assumption that alopecia areata is not a parasitic affection All that is required to cure it is a stimulus, and this is supplied by the superficial inflammation of the skin induced by the iron light, it extends along the hair follicles to their depths and stimulates the roots of the hair to renewed proliferation He gives the details of 6 cases thus treated with the iron "triplet" or 'dermo" lamp (See abstract of his previous communication on the subject, page 1119 of vol xli) Another promising field for the cold iron light is in superficial disinfection of the skin This light does not require preliminary compression of the part

58 Immunization of Consumptives with a Bovine Tuberculin—Spengler makes a tuberculin from bovine material which has very pronounced therapeutic value, while the reaction that follows its use is like that of very weak human tuberculin He calls it Perlsucht Original tuberculin (P T O) It is the filtered bouillon in which Perlsucht bacilli have been grown until they formed a very thin film over the surface. The bouillon is evaporated to one half, the missing fluid substituted by glycerin The initial dose is 1 mg diluted with 9 mg of a 5 per cent carbolic solution The injection is made centrifugally in the forearm, and is repeated, doubled, when every trace of the consecutive edema has vanished In case of great debility he rubs the tuberculin into the skin of the arm instead of injecting it He has found this percutaneous method especially valuable for acute tuberculosis in children He uses it also at times for the Koch tuberculin He combines the two in his new technic and calls a patient cured when he can take an alternating dose of 100 mg P T O and 100 mg tuberculin (Koch's T O A) without reaction, and constantly negative sputum findings By this technic the course of treatment with tuberculin can be very much shortened and more complete results attained There is absolutely no danger from the Perlsucht tuberculin The very first doses confer marked immunity Spengler believes that human and bovine tuberculosis were originally one, but that the bacilli have adapted themselves to their hosts until each has become the vaccine material for the other The Perlsucht toxins are much less virulent for man than human tuberculosis toxins

59 *Decapsulation of the Kidneys*.—Rosenstein reports 6 cases from Israel's clinic and sifts Edebohls' published material He concludes that all the cases cured by decapsulation of the kidney were merely inflammatory processes, due to abnormal movability of the organ Bright's disease is never unilateral, and the unilateral cases cited as evidence of the efficacy of the treatment must have been merely inflammation of a wandering kidney In severe Bright's disease, decapsulation of the kidney has a mortality record of 26 per cent Permanent cure has not been obtained in a single instance, and in the cases in which improvement was noted the edema persisted in one case and the albumin and tube casts in the urine In another case the headaches and scotoma persisted unmodified

63 *Anomalies in Chest Wall*.—Bäumler has sometimes found that the diagnosis of tuberculosis was based on abnormal percussion findings due solely to anomalies in the bony frame of the thorax, while the lungs were sound in reality In examining patients, special attention should be paid to the sym metry of the halves of the thorax, both sitting and standing The size, shape and depth of the supraclavicular regions on each side should be compared Slight scoliosis may cause the bulging of the rear portion of the upper ribs, with consequent abnormal percussion and auscultation findings, although the lungs may be perfectly sound It is a good plan to inspect the seated patient from behind, comparing the sagittal diameter of both sides of the chest, and tracing the spine its entire length An irregular configuration of the "shoulder girdle" is responsible for many abnormal findings on percussion The anomalies in the chest wall usually entail a displacement of the heart When the spine is abnormally straight, the front intercostal spaces are liable to be very wide This pushes the sternum up and the heart lies with a greater portion of its surface parallel to the wall of the thorax than in normal conditions The apex beat is broader and stronger The reverse occurs when the spine is unduly curved, and its sideward curve also has an influence on the position of the heart The organ may be perfectly sound, but these unusual positions may simulate hypertrophy of the left ventricle, especially in rapidly growing young persons with an 'excitable heart'

64 **Temporary Exposure of Stumps in Complicated Fractures.**—At Wölfler's clinic it is the practice now in severe, complicated, septic fractures to avoid amputation, if possible, by freely exposing the parts Five cases thus treated are described in detail The fractured leg or arm was turned back on itself in such a way as to make the wound gape and the fractured stumps project, the stumps held well apart by antiseptic sponges This allows better inspection of the wound does away with all menacing recesses and dead spaces and injury of the soft parts from the jagged stumps Necrotic tissues can be more readily removed and drainage facilitated When mere incision and drainage prove ineffectual, this opening up of the region may control the severest infection and save the limb after failure of all other measures It is so simple and effectual that it can be applied even without waiting to try other measures, in certain cases, and may save many a limb otherwise doomed to amputation

65 **Results of a Single Carlsbad Gallstone Course**—Fink has been practicing at Carlsbad for about a dozen years He reports his observation of 263 cases of gallstones in which a single course of treatment was taken In the majority of cases the gall bladder did not cause any symptoms The disturbances in the liver predominated, and had been the incitement to the Carlsbad course A single course resulted in an apparent permanent cure in 72 83 per cent of a former series of cases and in 87 33 per cent of the present series Its efficacy is limited by long continuance of the affection, by a superposed infection and by chronic occlusion of the bile duct Hence the importance of early diagnosis and treatment

67 **Odor of Infants' Feces**—Selter comments on the rather agreeable, acid, aromatic odor of normal breast milk stools, due to the fat acid and lactic acid and absence of albumin putrefaction Any change from normal is evident at once in the odor Cow's milk stools are always pasty, whitish, alkaline and have a true fecal odor In mucous catarr of the intestines the stools smell more like wet hay, when digestion is good, but this odor is overshadowed by putrefaction or fermentation The nose is thus able to determine conditions in the digestive tract, sometimes before they can be revealed by any chemical tests, thus disclosing impending fatty diarrhea, fermentation of carbohydrates or of albumin, etc

69 **Hygiene of Cigar Smoking**—Bamberger classifies smokers as the "dry" and the "wet" The "dry" smokers are those who hold the cigar in their lips without wetting it with saliva This is free from the dangers of "wet" smoking—that is, allowing the cigar to soak in the saliva The saliva dissolves out of the tobacco many harmful substances which are swallowed and help to induce tobacco poisoning Alcohol in the stomach, even in minute amounts, aids in the dissolving and rapid diffusion of the swallowed poisons All cases of tobacco poisoning probably have occurred in "wet" smokers Cigarettes are not wet in this way so much, their harmfulness is mainly in the large number used and the swallowing of the smoke Chewing tobacco contains so little nicotin that it can scarcely be regarded as directly harmful, especially as it lacks the products of combustion When nicotin poisoning from this source does occur, it assumes a special type, a painful weakness, hallucinations, tendency to suicide, with various sensory disturbances (deafness, loss of sense of taste) and prosopalgia, neuralgia Erb has recently noted a connection between arteriosclerosis and tobacco (see page 232), and Bamberger has had occasion to observe an attack of angina pectoris, with other manifestations of arteriosclerosis in a "wet" smoker of 40 Erb has also informed him in regard to a still later case in a young man, a pronounced "wet" smoker, but free from other taints Smokers should be warned to keep their cigars dry and to take them out of the mouth between the whiffs Thoms has recently patented his method of preventing tobacco poisoning It is based on the fact that certain iron salts hold in combination the bases of tobacco smoke Cotton impregnated with ferric chlorid is an efficient filter for this purpose It holds back 77 78 per cent of the nicotin and its bases, and 86 11 per cent of the ammonia The ethereal benz oil and surphur hydrate are completely held in combination and none escapes A tampon of cotton dipped in ferric chlorid applied to the tip of the cigar will thus afford efficient protection against tobacco poisoning It is even affirmed that it improves the flavor of a cheap cigar making the flavor more like that of genuine Havana tobacco on account of the effacement of so much of the nicotin and of the rank smelling chemicals in the cheap tobacco

THE PELVIC URETERAL SHEATH

ITS RELATION TO THE EXTENSION OF CARCINOMA CERVICIS UTERI *

JOHN A SAMPSON M D

Resident Gynecologist the Johns Hopkins Hospital Instructor in Gynecology Johns Hopkins University

BALTIMORE

During the last year and a half I have been studying the extension of carcinoma cervicis uteri with special reference to its bearing on the more radical operations for that disease These studies[1] have demanded a knowledge of the anatomy and physiology of the neighboring structures of how the disease invades these parts, and especially the effect of the more radical operations on such organs as the bladder ureters rectum and other pelvic structures

In studying cross sections of the parametrium of those cases in which the lower ends of the ureters have been resected in order to obtain a wide excision of the primary growth, an opportunity was afforded not only of determining how the growth invaded the parametrium, but also its relation to the ureters In these cases it was noticed that the ureters were inclosed in a sheath which seemed to be derived from the tissue along or through which the ureters pass, and served as a protection to the ureters from the invasion of the carcinomatous growth

Waldeyer[2] has called attention to the fact that there is pictured in Krause's anatomy longitudinal muscular bundles which extend from the bladder up on the ureter, but the cut is not accompanied by any description He describes them as longitudinal muscular bundles which are united to each other by connective tissue and separated from the ureter by a space which can be injected This sheath has a thickness of 5 to 75 mm, and he says extends from 3 to 4 cm up along the ureter The lumen he considers to be a lymph space

Disse[3] refers to Waldeyer's sheath, and says that these muscular bundles, which are greatly hypertrophied, do not come from the bladder, as they appear to do, but from the ureter, and suggests that their hypertrophied condition, as well as the space between them and the ureter, arises from the contractions of the bladder pulling on the outer ureteral coat

If the abdominal portion of the ureter is exposed at autopsy and partially freed from its surrounding tissue and traction made on it, it can be drawn out from what is apparently a sheath, which seems to be a part of the subperitoneal connective tissue, and is continuous with that surrounding the kidney above and accompanying the ureter into the pelvis below Cross sections of the abdominal portion of the ureter, with its surrounding tissue, show that the ureter lies in the subperitoneal adipose and fibrous tissue, and that this tissue forms a very imperfect and rather indefinite sheath about the ureter, and it usually requires some play of the imagination to make out a definite ureteral sheath from cross sections of the abdominal portion of the ureter If the dissection is carried down into the pelvis, this apparent ureteral sheath becomes more definite, so much so that it may be split open and the ureter shelled out from it On reaching the bladder the lower end of the ureter seems to be reinforced by muscle bundles extending from the bladder up along the ureter, and which have been referred to

On stripping the peritoneum from the side of the pelvis it will be noticed that the portion of the ureter above the parametrium may be carried down with the peritoneal flap thus formed This portion of the ureter will be referred to as the subperitoneal portion while that below the entrance of the ureter into the parametrium may be called the parametrial portion of the ureter

Cross sections of the subperitoneal portion of the ureter show that it is surrounded by a fibrous sheath which is derived from the tissue along or through which the ureter passes, and here is adherent to the peritoneum, on that account the ureter, with its sheath, may be dissected away from the walls of the pelvis with the peritoneum This is shown in Figure 1, which represents a cross section of the ureter taken about 1 5 cm above its entrance into the parametrium This sheath is better developed in some cases than in others, and by cross sections one may follow it above the brim of the pelvis in one case, while in another case the sheath around the entire subperitoneal portion of the ureter may be poorly developed Cross sections of the parametrial portion of the ureter show how the sheath accompanies the ureter through the parametrium, or, to express it more correctly, how there is formed about the ureter a sheath from the tissue along or through which the ureter passes, is shown in Figure 2

---

[2] Waldeyer Ureter-scheide Verhandlungen der Anatomischen *Gesellschaft* 1892 259 260

[3] Disse Von Bardeleben, Handbuch *der Anatomie* Gustav Fischer Jena 1902 vol vii No 1 pp 107 109

Cross sections of the lower 1 to 2 cm of the ureter demonstrate that this portion of the ureter is surrounded by muscle bundles which also give rise to a sheath, and which Waldeyer[2] claims extends up along the ureter for a distance of 3 to 4 cm In the cases which I have studied the muscular sheath has not extended over 2 cm above the bladder Disse[3] claims that these muscles arise from the ureter and not from the bladder, as they appear to do See Figures 3 and 4

The pelvic portion of the ureter is surrounded by a sheath which is derived from the tissue along or through which it passes Near the bladder this sheath is composed mostly of muscle fibers As one examines cross sections higher up, the muscular fibers gradually disappear and one finds that another sheath appears which fuses with the muscle fibers, encircling the upper ends of them and is continued above as the fibrous sheath previously referred to It is difficult to determine the origin of the muscular fibers about the lower end of the ureter They apparently arise from the bladder and I think that this is true for some of them, on the other hand, one can see from cross sections taken at different levels that others may arise from the outer coats of the ureter, as Disse[3] claims

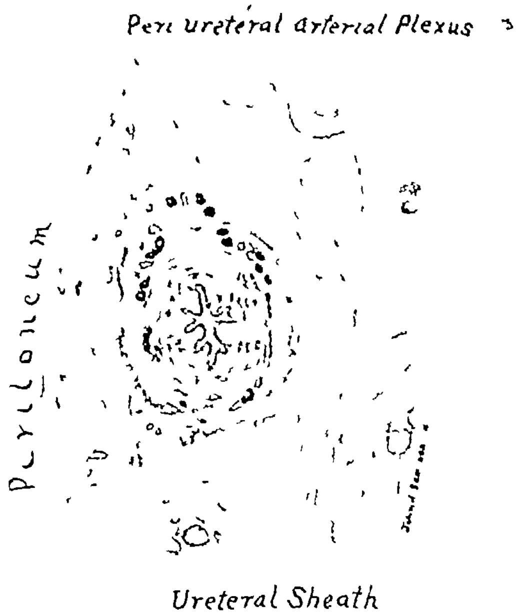

Fig 1 —Transverse section of ureter with its sheath taken 1 5 cm above its entrance into the parametrium ×5 The internal iliac artery was injected one hour after death, with a 15 per cent solution of gelatin colored with ultramarine blue The large vessels of the periureteral arterial plexus are shown contrasting with the smaller branches in the walls of the ureter The inside of the sheath is filled with adipose and fine fibrous tissue in which are imbedded the periureteral vascular plexuses

The structure of the sheath is dependent on the structure of the tissues along or through which the ureter passes Near the bladder one finds muscular fibers predominating, while higher up the sheath is composed of fibrous tissue, with an occasional muscle bundle The thickness of the sheath varies in different places, and in different cases, and is dependent on the tissue about it as may be seen by referring to the illustrations The lumen of the sheath is filled with adipose tissue and strands of fibrous tissue and contains the vascular ureteral plexus One finds in the sections of this sheath empty spaces, which in some instances may be lymph spaces but in nearly every instance which I have seen appeared more like artefacts A hypodermic needle may be inserted along the ureter and colored fluid forced into the tissue about the ureter, and this will follow the course of the ureter, indicating that this sheath restrict-

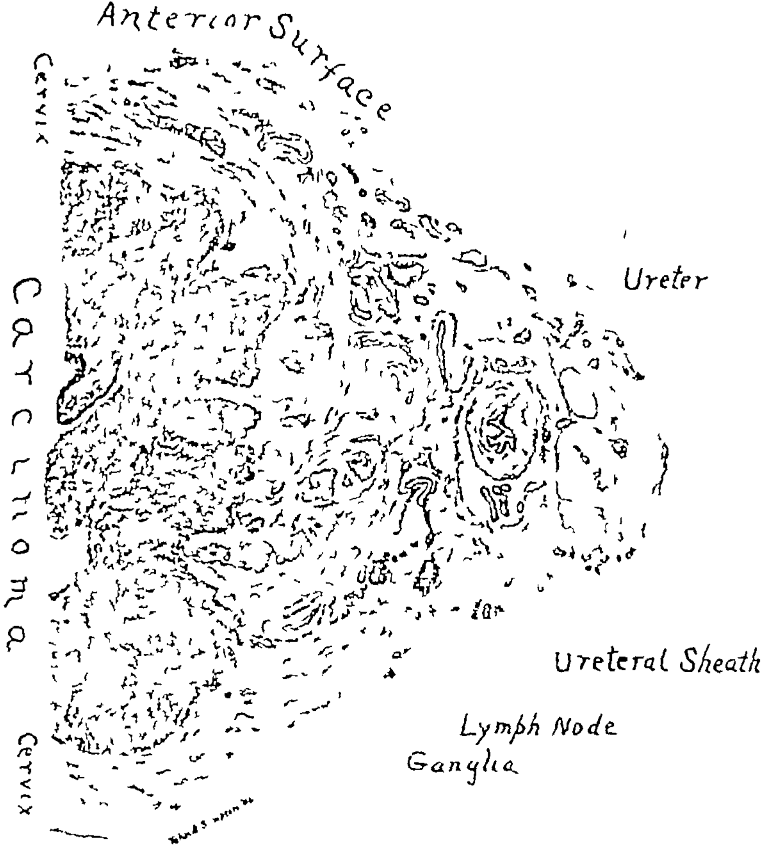

Fig 2 —Transverse section of ureter with its sheath taken about in the middle of the parametrium ×2¼ Transverse section of right parametrium and one-half of the cervix from a specimen of hysterectomy for carcinoma cervicis uteri in which the lower portion of both ureters was sacrificed and the renal ends of the ureters implanted into the bladder The ureteral sheath is derived from the tissue along or through which the ureter passes, and here consists of fibrous tissue with a few fine muscle bundles at the upper end Within its walls can be seen the larger vessels of the periureteral vascular plexuses in cross section

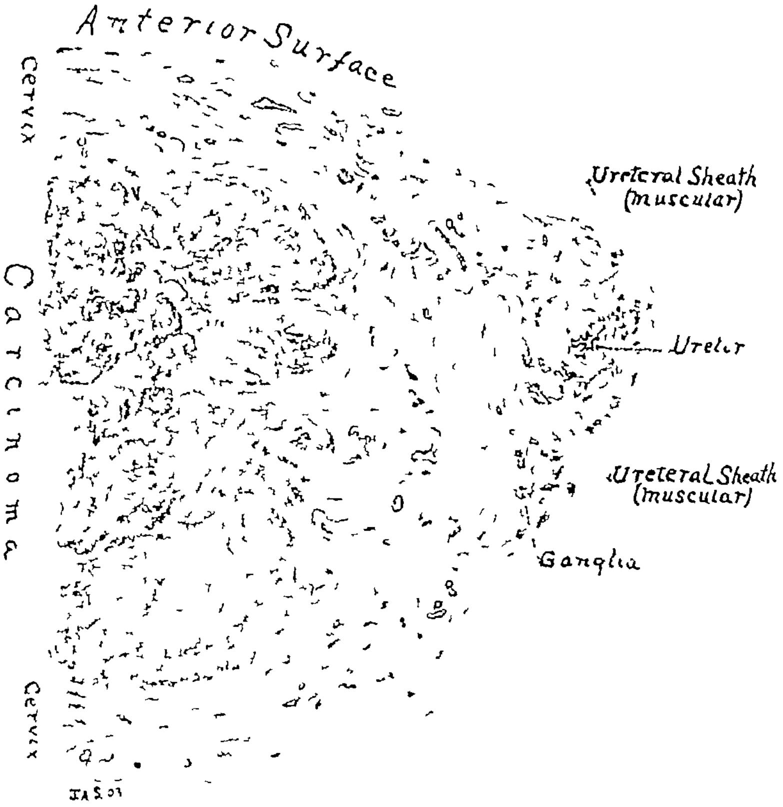

Fig 3 —Transverse section of ureter with its sheath taken just above the bladder ×2¼ From the same specimen from which Figure 2 was drawn As one can see the ureter at this level is surrounded by muscle bundles The ureter at this level is very near the cervix and it would take but little involvement of the parametrium either by direct extension or metastases for the cancer to reach or extend beyond the ureters

its spreading into the surrounding tissues and forces it to extend along the ureter

ORIGIN OF URETERAL SHEATH

It would seem that the sheath was due to the activity of the ureter, the peristalsis, with its sliding motion and distension and contractions of the ureter, forms out of the surrounding tissue a channel, the walls of which may be called a sheath In support of this view it may be said

1 The sheath, as such, is absent in the fetus

2 In a case of double ureter, in which the ureters were close together, one sheath was common to both

3 Its structure varies with that of the surrounding tissue

4 The ureter, deprived of its sheath, may form another from the tissue in which it becomes imbedded A patient was readmitted to this hospital in April of this year with a recurrence of carcinoma cervicis uteri about the left ureter At the first operation, six months before, the ureters had been freed and the ureteral sheath removed with the uterus and growth The recurrence, which was about the size of a hen's egg, was removed with the lower 4 cm of the ureter, and in studying the specimen it was found that a new sheath had formed about the ureter from the tissue in which it had become imbedded

5 The sheath is developed best in parts where there is opposition to its contractions and expansions, as in the pelvis, while in the abdomen, where the ureter lies in loose adipose and fibrous tissue, which offers very little resistance to the peristalsis of the ureters, the sheath is imperfectly formed or absent

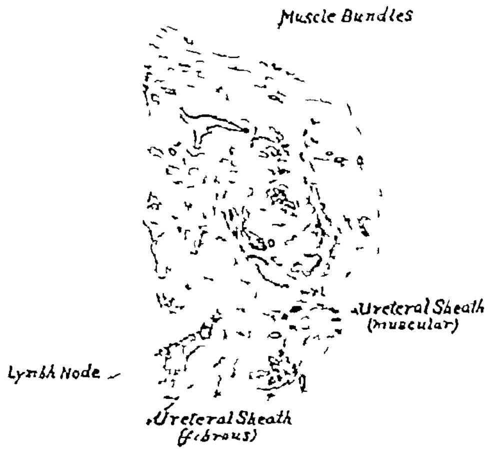

Fig 4—Transverse section of the ureter showing the relation between the fibrous portion of the ureteral sheath and the muscular portion ×2¼ Transverse section of a portion of the parametrium from the same specimen from which Figures 2 and 3 were made, and about half way between the two In the outer wall of the ureter can be seen heavy muscle bundles suggesting that the muscular sheath (Waldeyer) arises from the ureter as Disse claims on the other hand, other muscle bundles may be seen alongside of the ureter which may come from the bladder (?) Outside the ureter and the remnants of the muscle bundles can be seen a fibrous sheath which blends with the muscular sheath and gives rise to the fibrous sheath in Figure 2

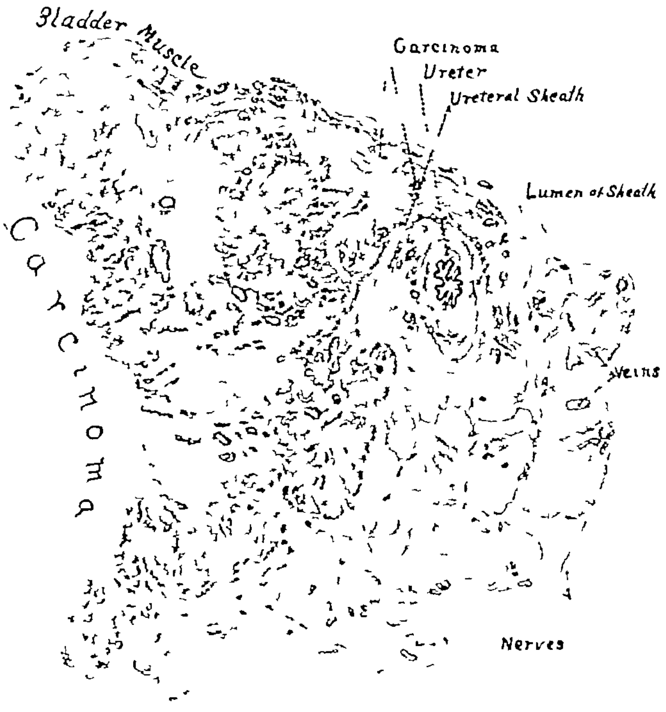

Fig 5—Demonstrating the effect of the invasion of the ureteral sheath by carcinoma cervicis uteri, ×2¼ Transverse section of the right parametrium and one-half of the cervix from a specimen of hysterectomy for carcinoma cervicis uteri in which the lower portion of the right ureter was sacrificed and the renal ends of the ureter implanted in the bladder

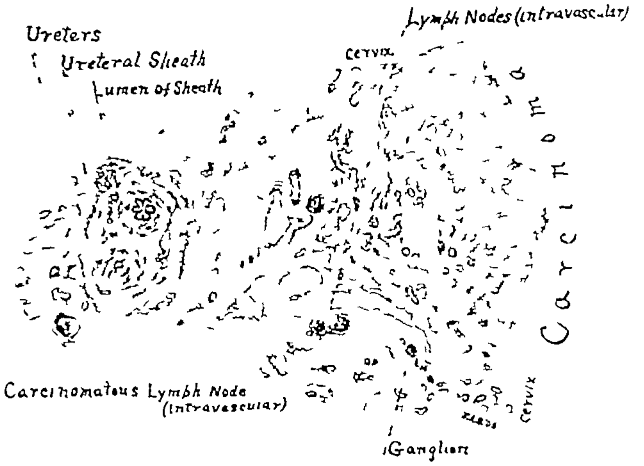

Ureters

Carcinomatous Lymph Node (intravascular)
Ganglion
Cervix

Fig 6—Demonstrating the relation between a metastasis to a minute parametrial lymph node and the ureter ×2¼ Transverse section of left parametrium and portion of the cervix The double ureter has but one ureteral sheath instead of two thus suggesting that the sheath is derived from the pelvic structures along or through which the ureter passes and not from the ureter Four lymph nodes are shown, and the one situated lateral and posterior to the double ureter is carcinomatous

RELATION OF THE URETERAL SHEATH TO DISEASED CONDITIONS

One can see how the sheath would protect the ureter from inflammatory processes and new growth On the other hand, thickening of the sheath from these diseased conditions might interfere with the function of the ureter An interesting condition arises where a stricture occurs at the vesical end of the ureter The ureter becomes distended and frequently very tortuous, and sometimes kinked Normally one finds certain constrictions in the ureter, one below the kidney and another at the brim of the pelvis, apparently due to a thickening of the surrounding tissue (sheath) at this place Where a hydroureter occurs, these constrictions become more marked and the ureter markedly distended above and below the constrictions where the tissue about the ureter is loose and the sheath formation less perfect When a kinking of the ureter takes place it is apparently due to a rupture of the tissue surrounding the ureter, i. e., a hernia of the imperfect ureteral sheath with a protrusion of the ureter and consequent kinking of the ureter by the hernial ring thus formed.

RELATION BETWEEN CARCINOMA CERVICIS UTERI AND THE PELVIC URETERAL SHEATH

One realizes that the uterus is a relatively movable organ. On the other hand, the ureters follow the pelvic wall and near the bladder they begin to approach each other, so that the distance between the ureteral orifices is from 2 to 3.5 cm., varying in different cases and with the degree of distension of the bladder. As the ureters are relatively fixed, the relation between them and the uterus is dependent on the position of the uterus in the pelvis, whether in anti- or retroposition, high in the pelvis or in the descensus, and especially in the lateral positions of the uterus, for when the cervix is in the right side of the pelvis it will be much nearer the right than the left ureter, and vice versa. At the level of the internal uterine os the ureters may be 7 to 9 cm. apart and consequently would be some distance from the sides of the uterus; on the other hand, at the level of the external os they are *much nearer together* and their distance from the cervix may be less than 5 mm., depending on the size of the cervix and its position in the pelvis. It becomes evident that carcinoma cervicis uteri does not have to extend far into the parametrium either by direct extension or metastases, to reach or extend beyond the ureters.

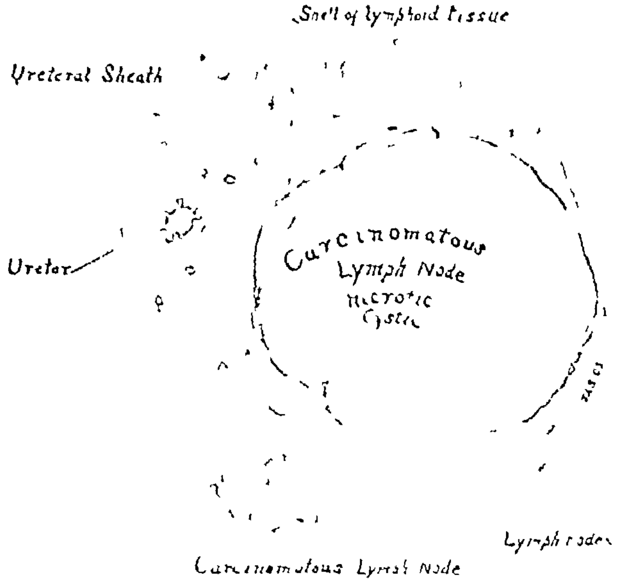

*Fig. 7.—Demonstrating the relation between a large carcino*matous lymph node and the ureter ×2½. From the same case as the section represented in Figure 6. This carcinomatous lymph node which had become necrotic and cystic is situated lateral to the right ureter and is the node sometimes found near the crossing of the uterine artery and ureter.

The relation between carcinoma cervicis uteri and the *ureters manifests itself clinically, in renal insufficiency* resulting from a compression of the ureters by the growth and in the frequency of accidental injury to the ureters occurring during operation for the removal of the growth, there having been in this hospital 19 cases of accidental injury to the ureter in 156 hysterectomies for carcinoma of the cervix, as compared with only 11 similar injuries in 4,513 other major gynecologic operations.

A study of fifteen specimens removed by the more radical operation, i. e., where an attempt is made to remove the lymphatics from the sides of the pelvis and with them the uterus and growth and all the parametrium, either dissecting the ureters free or else resecting the lower ends of them and implanting the renal end in the bladder, has shown that in twelve cases the growth has extended beyond the uterus, thus clearly demonstrating why hysterectomy so seldom cures this condition. In seven of the twelve cases there was a direct extension of the growth from the cervix. There were metastases to the parametrial lymph nodes in four cases, and metastases have been found in the other pelvic lymph nodes in six out of twelve cases in which they have been studied.

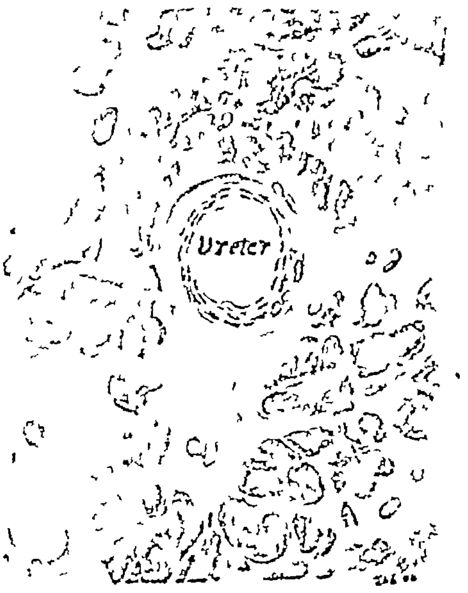

Fig. 8.—Demonstrating the invasion of the ureteral sheath by carcinoma cervicis uteri with resulting compression of the ureter ×1. The ureter is surrounded by the growth. The sheath being derived from the tissue through which the ureter passes can not be differentiated from it and the effect of the invasion of the growth into the sheath is to compress the ureter giving rise to hydroureter above.

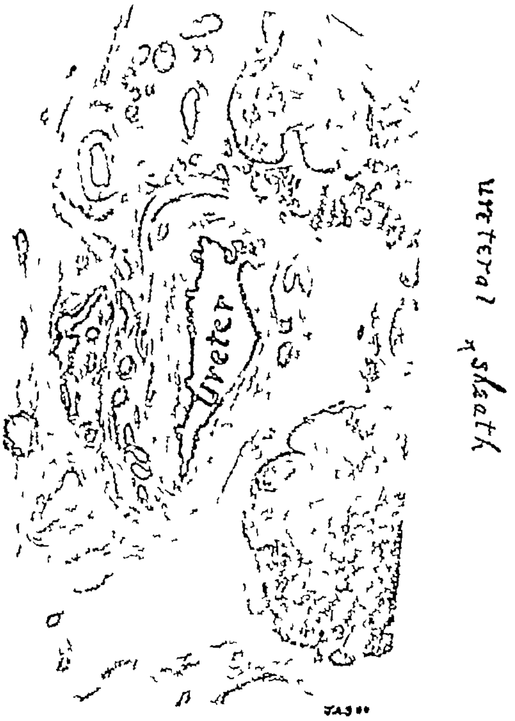

Fig. 9.—Demonstrating the hydroureter caused by the invasion of the ureteral sheath by carcinoma cervicis uteri ×1. From same specimen as the one shown in Figure 10 demonstrating the hydroureter caused by the ureteral sheath which has been invaded by the cancer.

Pathologically, the close relation between carcinoma cervicis uteri and the ureters shows itself:

1. In the distension of the cervix by the growth, thus diminishing the distance between the ureters and the cervix.
2. In the direct extension of the growth from the cer-

vix into the parametrium. As the distance between the ureter and the cervix may be less than 5 mm. in the lower portion of the parametrium, which, unfortunately, may be the part of the parametrium first involved by a direct extension of the growth, it takes but very little involvement of the parametrium to reach or extend beyond the ureters.

3. In the metastases to the parametrium which may occur:

(*a*) In the large parametrial lymph node occasionally found at the place where the uterine artery crosses the ureter.

(*b*) In the small parametrial lymph nodes scattered throughout the parametrium.

(*c*) In (intravascular?) lymph nodes which apparently protrude into the lymph channels like sponges and may be present in large numbers in these cases. These may be true intravascular nodes or the apparent lymph channel may be an artefact.

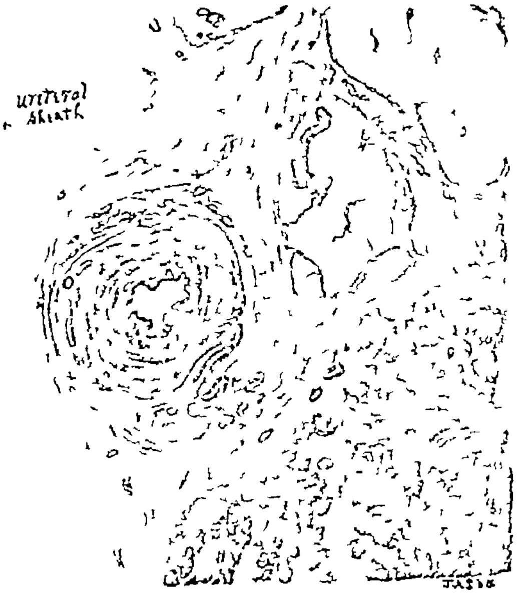

Fig. 10.—Demonstrating the reformation of the ureteral sheath about a ureter which had been freed in a more radical operation for carcinoma cervicis uteri. ×4. The lower 4 cm. of the left ureter was excised with a recurrence of carcinoma cervicis uteri. Primary operation six months before, when both ureters had been freed from their sheaths.

(*d*) In the other structures of the parametrium, as sheaths of nerves, ganglia, lymph spaces, etc.

Whatever the form of the invasion of the parametrium it does not have to extend far in order to reach the ureter. In Figure 5 is a drawing from a specimen in which the growth has extended out from the cervix and has involved the ureteral sheath and one can see that the latter has become hypertrophied, thus better protecting the ureter, while in Figures 8 and 9, from another case, the growth has surrounded the ureter with its sheath, compressing and invading the sheath, thus giving rise to a hydroureter above. In Figure 6 is a drawing showing a metastasis to one of the minute (intravascular?) parametrial lymph nodes, which is situated lateral to the double ureter. One finds in the parametrium of these cases minute parametrial lymph nodes which may have a diameter of not over 1 to 2 mm. The nodes have the same structure as the larger lymph nodes found throughout the body, and cancer may metastasize to them without causing any increase in their size. In some cases these nodes give the impression of having been made in a lumen, about them are apparent lymph spaces and the picture is that of an intravascular lymph node which protrudes into the lumen of the lymph channel like a sponge. These nodes may be the same as the other minute lymph nodes above referred to and the intravascular appearance may be an artefact. The entire subject needs further study.

An invasion of the larger lymph nodes sometimes found in the parametrium is shown in Figure 7. In this instance the node was situated lateral to the ureter and one can see that the portion of the ureteral sheath next to the node is markedly thickened.

ABILITY OF THE URETERAL SHEATH TO RESIST THE INVASION OF CARCINOMA CERVICIS UTERI

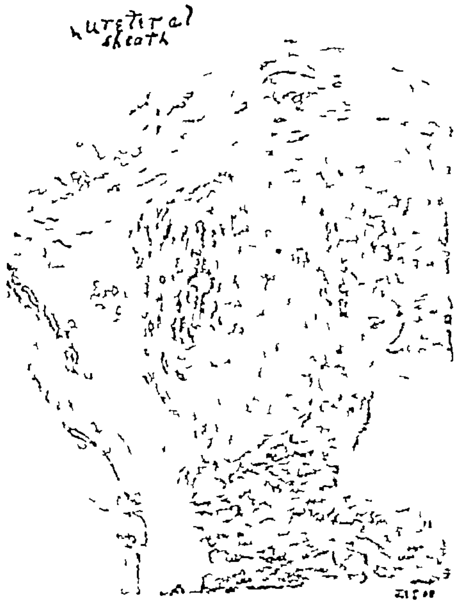

Fig. 11.—Demonstrates the destruction of a new formed ureteral sheath and the invasion and compression of the ureter by recurrence of carcinoma cervicis uteri. ×4. Same specimen as one shown in Figure 10, but at lower level.

As has been stated, the ureteral sheath is derived from the tissue along or through which the ureter passes, and on this account it is no more able to resist the invasion of carcinoma cervicis uteri than the rest of the tissue from which it is made, and its apparent ability to resist the invasion of cancer does not depend on any quality inherent in it, but on the nature of the growth. Growths differ greatly in their manner of invading the surrounding parts. One will find a large cancer, which in its growth tends to become encapsulated. The expansion of the growth seems to convert the surrounding tissues into a capsule, and the direct invasion of the surrounding tissue may take place, apparently, very slowly. On the other hand, in another growth there may be no evidence of expansion or encapsulation, but the growth extends in all directions into the surrounding parts, causing but a very little increase in the size of the parts involved. In Figure 5 the invasion of the ureteral sheath has apparently caused a hypertrophy of the sheath which would serve to protect the ureter, but later this very hypertrophy may compress the ureter and cause renal insufficiency. A similar condition is shown in Figure 7, in which the wall of the sheath next to the cancerous lymph node has become greatly hypertrophied, thus apparently protecting the ureter from an invasion of the growth. In Figures 8 and 9, from another case, one can see that the ureteral sheath apparently is affected by the invasion of the cancerous growth in no way different from the rest of the surrounding tissue

In another instance in which I had the opportunity of studying the relation between the growth and the ureter, I found that the growth had apparently broken into the ureteral sheath and had extended along the ureter within its sheath, and the latter in places was intact

REGENERATION OF THE URETERAL SHEATH

In November, 1903, I removed a cancerous uterus by one of the more radical operations The pelvic lymphatics were removed with the uterus and growth and the parametrium out beyond the ureters The latter were shelled out from the sheath, which was incised along its lateral surface A study of the specimen showed metastases both to the parametrium and pelvic lymph nodes, while the primary growth was apparently entirely removed The patient returned in April 1904, complaining of some indefinite pain in the left side of the pelvis Pelvic examination showed a lump about the size of a hen's egg apparently about the lower end of the left ureter In April, 1904, an exploratory operation was made and this lump proved to be a return of the cancer, probably from a minute lymph node which had been overlooked and was situated laterally and below the left ureter The mass, about the size of a hen's egg was removed with the lower 4 cm of the ureter and the renal end of the ureter was implanted in the bladder

An interesting pathologic feature about the case was that a new ureteral sheath had formed from the tissue in which the barred ureter had become imbedded as shown in Figure 10, and that this latter had become invaded by the cancerous growth as shown in Figure 11 where one can see that the growth has destroyed the portion of the ureteral sheath next to it and has pushed the ureter against the outer wall of the sheath, and soon the left kidney would be thrown out of function

CONCLUSIONS

1 The pelvic portion of the ureter is surrounded by a sheath which is apparently derived from the tissue along or through which the ureter passes and owes its origin to the peristaltic movements of the ureter, thus causing intermittent pressure on its surrounding tissue In favor of the above it may be said (*a*) That the sheath as such is absent in the fetus (*b*) that in a case of double ureter in which the ureters were close together, one sheath was common to both, (*c*) that its structure varies with that of the surrounding tissue, (*d*) the ureter deprived of its sheath may form another from the tissue in which it becomes imbedded (*e*) the sheath is developed best in parts where there is opposition to its contractions as in the pelvis, while in the abdomen, where it lies in loose adipose and fibrous tissue which offers very little resistance to the contractions of the ureter, a definite sheath is imperfectly formed or absent

2 Near the bladder the ureter is reinforced by muscle bundles, some of which apparently come from the bladder, as described by Waldeyer while others are apparently derived from the outer coat of the ureter, as described by Disse These muscle bundles also form a sheath about the ureter, with which the sheath previously referred to fuses While the two may be considered different portions of one sheath, on account of their origin and the fact that the lower end of the fibrous sheath apparently encircles the upper end of the other they should be considered as separate structures

3 The formation of a sheath about the abdominal portion of the ureter is very imperfect and in places apparently absent, which may possibly be explained on the ground that the surrounding tissue is loose and on this account offers little resistance to the contractions and expansions of the ureter

4 The inside of the sheath is filled with adipose tissue and fine strands of connective tissue in which are imbedded the larger vessels of the periureteral vascular plexuses, and also possibly lymph channels

5 While this sheath protects the ureter from the invasion of inflammatory processes and new growths, at the same time the local thickening of the sheath may interfere with the function of the ureter, thus giving rise to hydroureter and renal insufficiency and predisposing the kidney to infection, and in cases of ureteritis helps form the thickened ureter found in these cases

6 Stricture of the lower end of the ureter demonstrates the imperfect formation of this sheath, as where the sheath is well formed expansion of the ureter is restricted, causing a stricture, while above this place the loose tissue (sheath) about the ureter may give way, permitting the tortuous condition and kinking of the ureter sometimes found in these cases, i e , a hernia of the ureter through its sheath

7 The ability of the ureteral sheath to resist the invasion of carcinoma depends more on the nature of the particular growth than any quality of the sheath, for the latter is derived from the surrounding tissue and behaves toward the growth as does the rest of the tissue about it (*a*) In some cases one finds a marked hypertrophy of the sheath, thus temporarily protecting the ureter, and later this hypertrophy may compress the ureter (*b*) In other cases the ureteral sheath may be invaded with very little or no apparent attempt at hypertrophy, while in one case studied the growth gained access to the inside of the sheath and extended along the ureter within the sheath

8 This sheath is of importance in operations in the pelvis, for if the integrity of the sheath is preserved, that of the ureter is assured On the other hand, freeing the ureter from the sheath unless done with great care, is attended with dangers of ureteral necrosis Also in ureterovesical implantations the ureteral sheath should be preserved and sutured to the bladder, thus not only protecting the ureter but what is also of great importance the tension of the implantation is relieved

---

EXCISION OF PART OF THE ILEUM AND ALL OF THE CECUM AND ASCENDING COLON

ILEUM AND TRANSVERSE COLON UNITED BY A NEW METHOD *

J SHELTON HORSLEY, M D

Professor of Principles of Surgery Medical College of Virginia
Surgeon to Memorial Hospital

RICHMOND, VA.

The various ingenious methods used at present to unite the divided ends of the intestinal tract are prima facie evidence that no one method is satisfactory in all cases The trend of surgical opinion seems in the direction of suture, as against mechanical appliances, and this results from the fact that an operative procedure requiring for its performance special apparatus is thereby handicapped When the appliance is one that must be left in the intestinal canal till healing has been completed additional disadvantages, such as gangrene and obstruction, at once suggest themselves Undoubtedly mechanical contrivances are sometimes indicated but such instances should constitute the exception and not the rule

---

* Read at the Fifty fifth Annual Session of the American Medical Association in the Section on Surgery and Anatomy and approved for publication by the Executive Committee Drs DeForest Willard Charles A Powers and J F Moore

In a previous paper[1] I have given results of experimental work in intestinal suturing and attempted to demonstrate the great advantages that the continuous suture penetrating all the intestinal coats has over the interrupted They are uniform pressure, splint-like action and rapidity of application, all of which have been gone into in some detail in the paper mentioned, and will not be taken up here As a result of this experimental work a new method o intestinal union was evolved, which is particularly applicable to intestines of small or unequal caliber, as it is in these cases that suturing is most difficult and stricture most disastrous In bowels of uniform and ordinary caliber there is probably no better method of union than by the Connell continuous or the Cushing right-angled suture, penetrating all coats

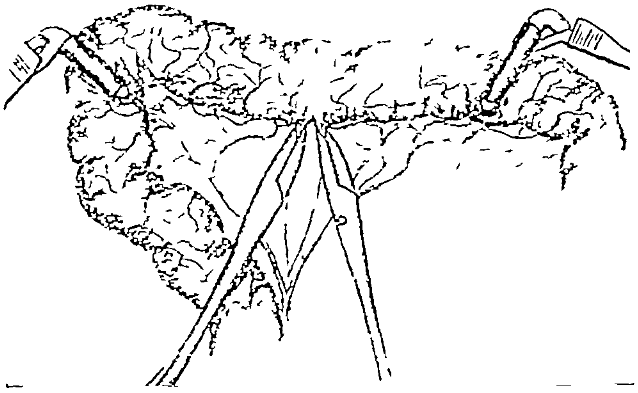

Fig 1

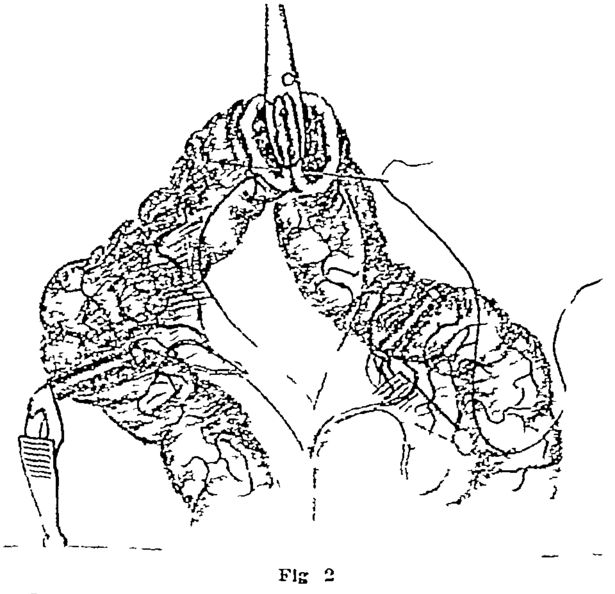

Fig 2

Intestines of unequal caliber frequently have to be united Not only does this condition obtain when the ileum must be joined to the colon, but it occurs pathologically after partial or complete obstruction in intestines of normally uniform caliber It is common knowledge that in cases of this character the bowel above the obstruction may become greatly dilated, when the surgeon is confronted with the serious problem of uniting the dilated segment to that of normal diameter Not only are the technical difficulties great, but, as pointed out by Treves, there is much danger of stricture resulting

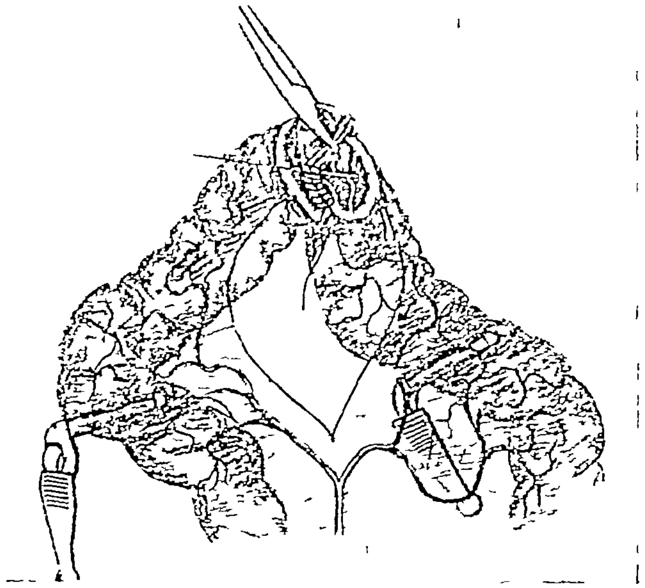

Fig 3

This new method seeks to simplify the technical difficulties and to obviate stricture in such cases, and in cases where the caliber, though uniform, is small The method will be described as applied to intestines of small diameter, then the slight modification necessary when intestines of unequal caliber are to be united will be given.

The intestinal clamps are placed on a single knot of a soft rubber tube used, as recommended by Ballance and Edmunds, to obtain coprostasis The mesentery is incised, in resection, a triangular portion may be removed The vessels at the mesenteric border of the intestine are clamped before being cut The forceps that clamp the vessels are also made to include both layers of perito-

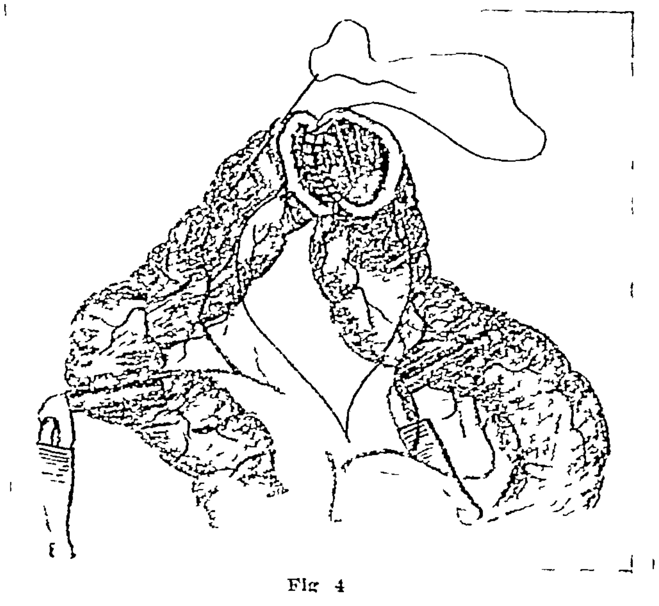

Fig 4

---

[1] Annals of Surgery Nov., 1903

neum as they separate from the mesentery to encircle the bowel The tissue within the bite of the forceps is ligated with fine silk, so drawing the peritoneum over the area of bowel usually devoid of a serous coat, and at the same time closing the vessels This stage is shown in Figure 1 Next the bowel is divided or resected, as the case may be, and the convex borders placed in contact and held in this position with hemostatic forceps An ordinary No 8 sewing needle threaded with No 2 braided silk, transfixes both walls of the intestinal ends about half way between the mesenteric insertion and the forceps (Fig 2) The suture is drawn through and tied

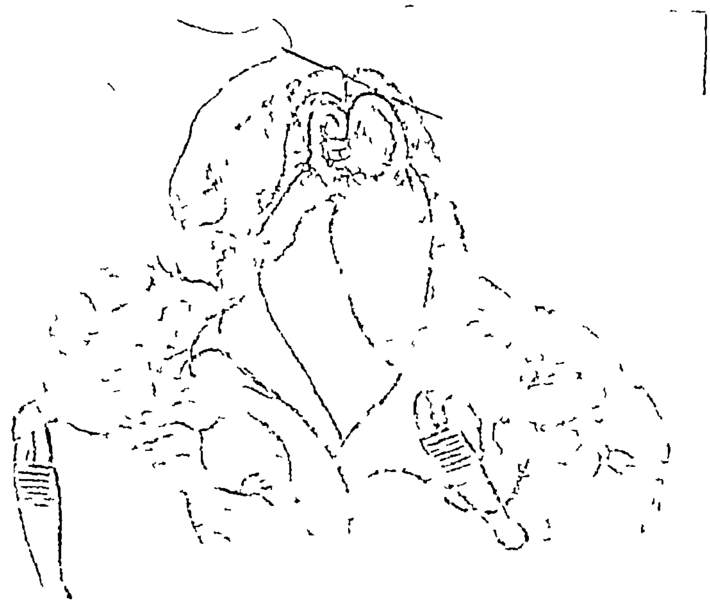

Fig 5

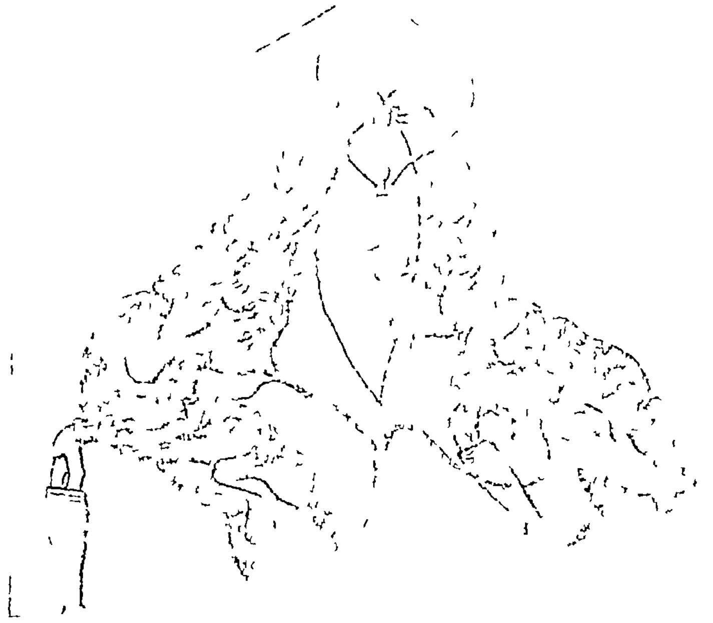

Fig 6

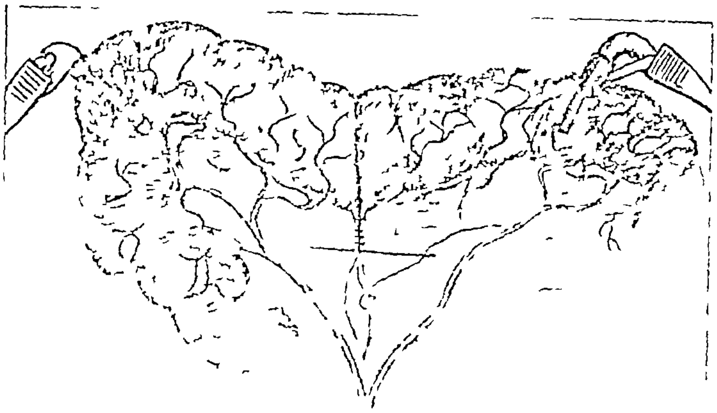
A portion of the intestinal walls forming a crescentic area the center of which is grasped by the hemostatic forceps, is now cut out with scissors, by cutting about one-third of an inch at a time and suturing the cut edges together with a continuous circular (overhand) stitch, penetrating all coats, and then cutting another one-third inch and suturing, and so on until the crescentic area is excised (Fig 3) Or the continuous Connell suture may be used, suturing first for a few stitches and then cutting The needle is inserted about six times to the inch and moderately firm tension is constantly kept on the thread with the left hand



Fig

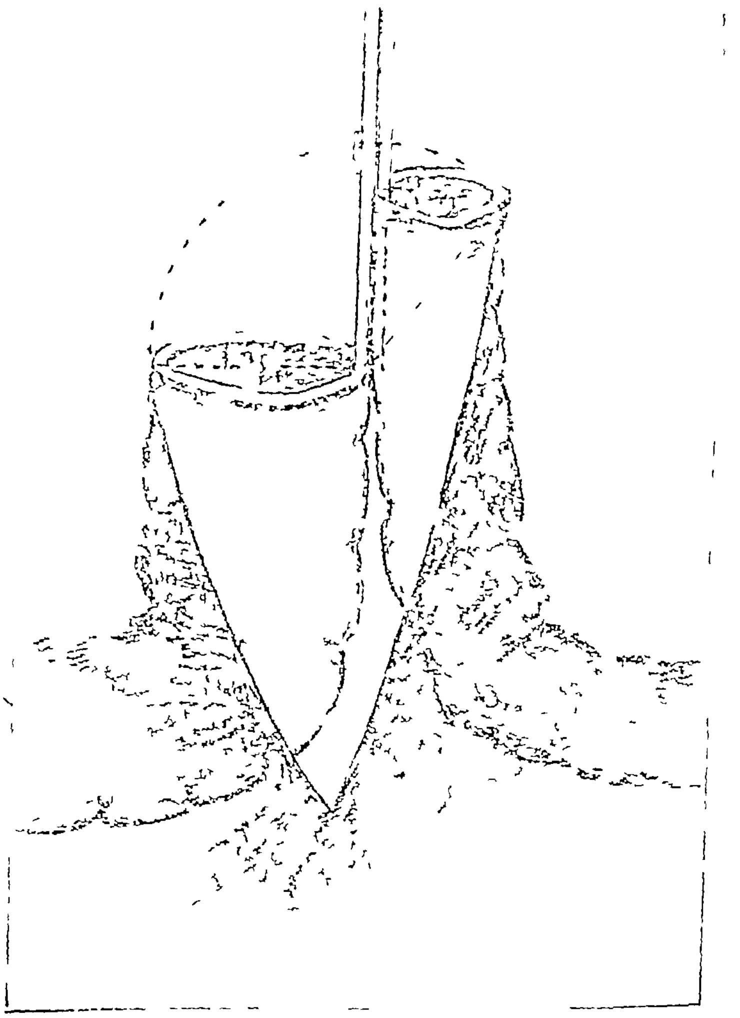


Fig 8

When this crescentic area has been removed, and the margins from which it was cut have been sutured in the manner described, the needle is thrust directly through the intestinal wall just to the right of its last puncture and emerges from the serosa The character of the stitch is now changed to a Cushing right-angled continuous suture, penetrating all coats, which readily inverts the remaining margins of the wound (Fig 4) The stitch is continued (Fig 5) with moderately firm traction on the thread When the first knot is reached it is invaginated, and the suture continued by two more insertions of the needle With these last two insertions of the needle as secure a hold as possible is obtained without penetrating to the mucosa The very last insertion is in the reverse direction of the other insertions, so that when the knot is tied it is partly buried (Fig 6) If desired it may be completely buried by a single mattress stitch, though I have never thought this necessary After this suturing is completed but little of the thread can be seen The bowel is then turned to its natural position, and with another needle, similarly threaded, the mesentery is sewed up with a continuous stitch (Fig 7) The needle is inserted in the mesentery at its junction with the bowel, and the first knot when tied acts as a mesenteric stitch It is placed close to the bowel though no attempt is made to include any portion of the intestinal wall in its grasp, as in the Mitchell-Heamner or Halsted mesenteric stitch

When bowel of unequal caliber is to be united, the two segments are clamped by taking a deeper bite on the small bowel than on the large, so when the mesenteric borders of both segments are lifted up these borders will be on the same level (Fig 8) One corner is caught with a hemostat and the suturing is begun at the other corner (Fig 9) All of the crescentic area is cut from the small gut except at the points where the hemostats are applied as here both bowels are clamped Otherwise the operation is finished as above described

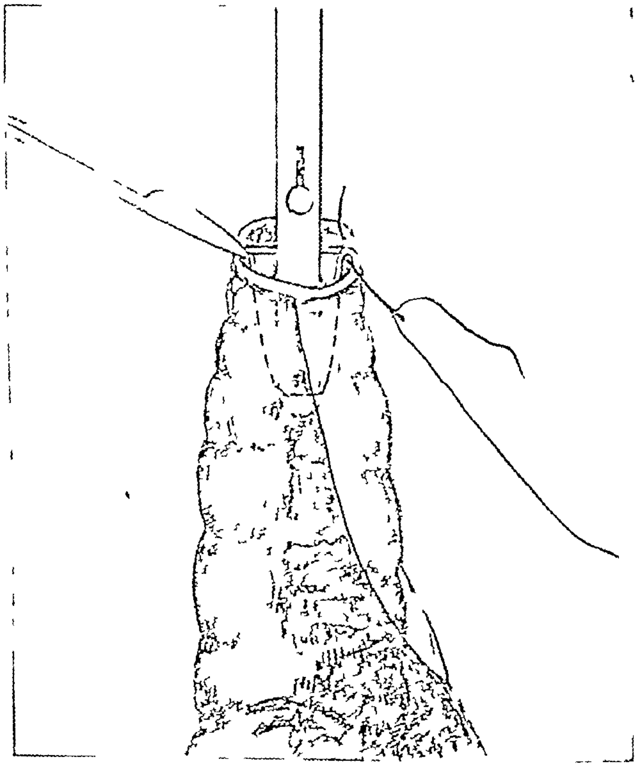

Fig 9

The following case may be interesting, not only from a surgical standpoint as involving a new method of operating but also pathologically for the tumor proved to be different from what it was thought to be at the time of operation

Mr P L, Mexican married cigarmaker aged 26 previous history negative has one child who is healthy There was a history of youthful dissipation before marriage His wife is healthy

History—Since 1900 he had been suffering from pains in the abdomen located chiefly on the right side and in the iliac region He had lost very much in weight a few months before coming under my care in April 1902 He was thin and there was considerable spasm of the abdominal muscles on the right side with the greatest tenderness apparently over the region of the appendix He was operated on April 7 1902 and the appendix removed Macroscopically, it showed the ordinary appearances of catarrhal appendicitis He was discharged three weeks after the operation in good condition, the wound having healed primarily For several months he improved and complained of little or no pain He gained materially in weight

About October, 1902, pains again set up of similar character to those from which he originally suffered They gradually increased He went to different physicians, who treated him for various ailments Continually growing worse, he finally came to me again, in May, 1903, a little more than a year from the time of operation His condition was pitiable He was excessively emaciated, and there were frequent paroxysms, from which he suffered intensely There was some pain all the time, but these attacks would come on during the day without any particular reference to what he had eaten, or to anything that he had done Another examination showed him to be in apparently normal condition, as far as kidneys, lungs and heart were concerned There was no evidence of any constitutional disease It was very difficult to make out anything in the abdomen, owing to his sensitiveness to pressure there, and to spasms of the muscles over the whole abdomen, particularly on the right side, consequently, examination was practically negative His bowels had been regular, there was some tympanites but no marked distension An exploratory incision was advised and this the patient readily consented to, with the understanding that any operation found to be necessary would be done

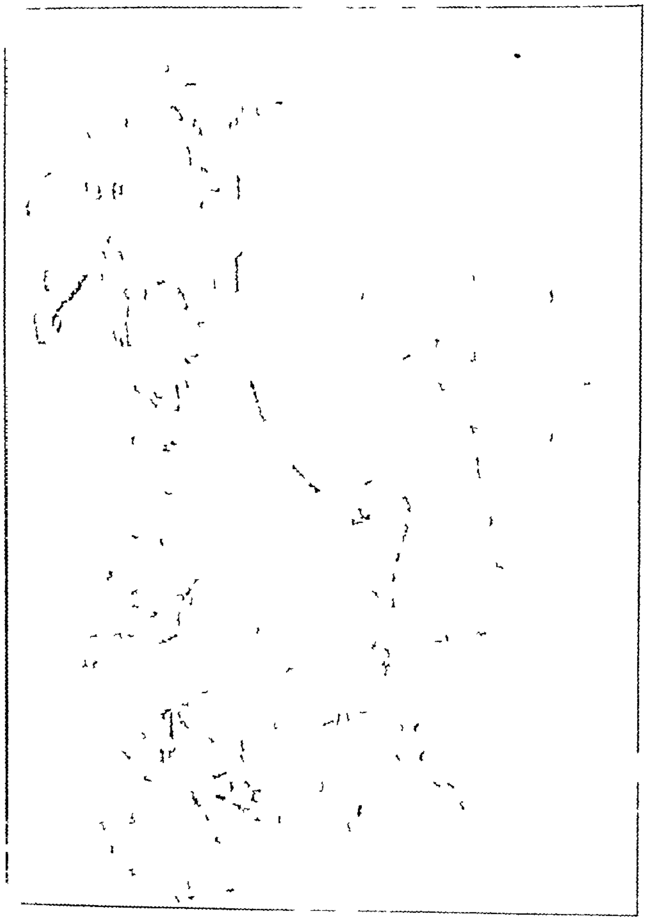

Fig 10—Photograph of specimen two hours after removal

Operation—June 2, 1903 A vertical incision was made through the outer edge of the right rectus muscle below the level of the umbilicus Cecum was adherent to the peritoneum at the site of the old operation scar made when the appendix had been removed. Cecum and most of the ascending colon were infiltrated by a neoplasm and greatly thickened. The glands in the mesentery were enlarged Nodules the size of buck shot, appeared in various portions of the colon and cecum About the middle of the colon a stricture had formed, which rendered the intestinal wall here very thick The photograph of the specimen (Fig 10), taken shortly after its removal, shows most of the points mentioned The pathologic process, supposed to be carcinoma, stopped at the upper part of the ascending colon The involved tissues were firm and elastic In order to remove the mesenteric glands, the last ten inches of the ileum were excised, though this intestine was not diseased The cecum and all of the ascending colon were cut away, going well into the healthy tissue of the transverse colon The vessels were very large They were ligated in sections But little blood was lost

The clamps used for coprostasis were covered with rubber tubing and once during the operation both clamps slipped, allowing some fecal matter to escape This was cleaned away as quickly as possible, but as the operation could not be done entirely extraperitoneally, owing to the short mesentery, infection of the peritoneum necessarily occurred An end to end union of ileum and transverse colon was made with suture according to the method described above for intestines of unequal caliber

The intestinal suture took sixteen minutes, which, with the dissection, ligating the numerous vessels, thorough toilet of the peritoneum, and suturing the abdominal wall, made the operation two hours in length A tube surrounded by gauze, and this wrapped with rubber tissue, was used as a drain.

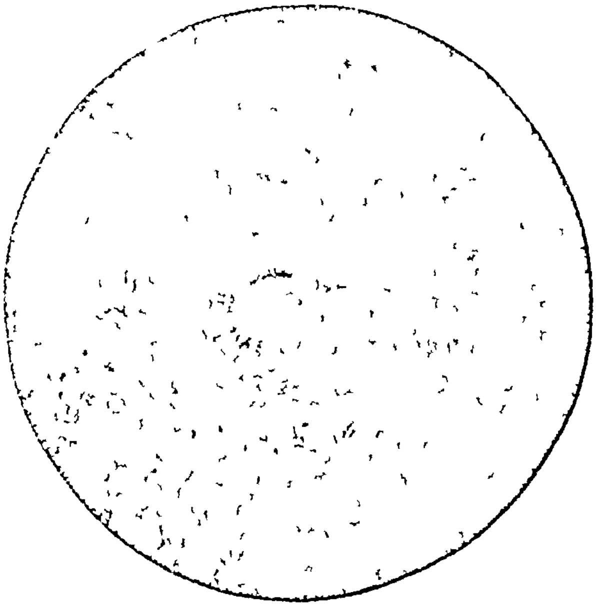

Fig 11 --Syphilis of the Intestine, thickened artery walls

The patient complained bitterly of pain as soon as he recovered consciousness, though pulse and general condition were satisfactory He passed gas from the bowel a few hours after the operation, and several large movements occurred during the first forty eight hours On the evening of the third day the temperature went up, drainage had practically stopped

In spite of thorough bowel movement, with no tympanites or indication of general peritonitis, the patient rapidly failed and died on the afternoon of the third day after the operation His clinical chart shows as follows

June 2, before operation—Temperature, 98, pulse, 78
June 2, after operation—Temperature, 98 4, pulse, 110
June 3—Morning temperature, 100 2, pulse, 105
June 3—Afternoon temperature, 101, pulse, 98
June 4—Morning temperature, 100 2, pulse, 100
June 4—Afternoon temperature, 102, pulse 128

Autopsy—Postmortem examination was made in the presence of a relative, and with the assistance of Dr A H White of El Paso About eight ounces of seropus had accumulated at the site of the incision, but was firmly walled off from the general peritoneal cavity by omentum and intestines There was no evidence of general peritonitis, and very slight tympanites The omentum was plastered over a portion of the suture line at the intestinal union, the site of the union itself making part of the wall of the cavity containing the seropus The union was in excellent condition, showing no leakage though it was slightly distended with gas and fecal matter A segment of the intestine including the union was removed, after separating adhesions, and thoroughly examined both by inspection and water pressure It was perfectly sound, without any apparent weak point The peritoneum over a portion of the removed segment was, of course, inflamed from the local infection Death was evidently caused by the local infection, which the patient's weak condition could not overcome Had the drainage been efficient or the patient's resistance greater, a fatal issue would probably not have occurred There was no satisfactory explanation for the drain not working

The photograph of the gross specimen shows some of the interesting features of the case (Fig 10) Particular attention is called to the stricture, to various nodules, and to two or three prominences in the mesentery, which were enlarged glands

A thorough microscopic examination of the specimen was made by Dr Greer Baughman, assistant pathologist to Memorial Hospital, to whom I am greatly indebted for the following report

Microscopic Examination of the Tumor—Pieces were taken from the tumor, from the intestinal wall and from the place where the tumor began to rise from the intestine These were hardened in the usual way, cut in collodion and stained with hematoxylin and eosin All of the sections showed a diffuse thickening of the arterial walls (Fig 11), and a proliferation of the endothelium lining the vessels, some of the smaller arteries seemed obliterated The thickening of the arterial walls was not limited to the small arteries

The tumor itself was almost entirely submucous There was an occasional infiltration of round cells through the muscle and in some places the superficial glands seemed to be worn away The cells composing the tumor were round A cheesy degeneration was noticed here and there In several of these cheesy nodes giant cells could be distinctly made out

The cheesy masses were made up of cell detritus, with a few nuclei The cells composing the tumor proper were irregular sized round cells, a few epithelioid cells were in the neighborhood of the cheesy masses

The thickening of the arterial walls, the presence of gumma like nodules, in which giant cells are noticed, and the submucous situation of the tumor led to the diagnosis of syphilitic gumma of the intestine

DISCUSSION

Dr O C Smith, Hartford, Conn—I congratulate Dr Horsley on his ingenious method of anastomosis, and also on his temerity to report a case which did not recover, and one where the diagnosis was made at autopsy Such cases are of vastly more interest than the simple ones which go on to a cure He refers to having operated for appendicitis Time was when nearly every physician and surgeon whatever else his failings, felt that he was proficient in obstetrics, but now nearly every surgeon believes that he can, at least, operate well for appendicitis Not infrequently the surgeon operating for appendicitis will encounter such a case as this for here in the region of the ileocecal valve is the most frequent location of cancer in the abdominal cavity We have had such cases at the Hartford Hospital where the most probable diagnosis was appendicitis and found instead carcinoma, and when a novice comes on such a case he may be at a loss to know what to do If he is timid or conservative he will content himself with performing colostomy above the obstructing growth If he is courageous he may attempt excision and entero enterostomy but by the time he has separated the ileopsoas fascia and dealt with the mesentery he is likely to be used up, but he still has to undertake the removal of the diseased portion of the intestine and perform the anastomosis He would have choice of several methods for the latter procedure, and he might not know which to select Had he better close the ends of both intestines and do a side to side anastomosis or should he close the end of the colon and implant the end of the ileum into its side, thereby imitating the natural junction of the ileum and cecum or should he bevel the end of the small intestine to make its circumference like that of the colon and do an end to end anastomosis' If he decided to use a mechanical device for the anastomosis, he would have to decide between those which are removed at the time of the operation as for instance, the Laplace clamp and those which are to be left in the lumen of the bowel, whether a button, a bobbin or a bone plate, and so it behooves every man who operates for appendicitis to equip himself with some definite plan for doing these more serious operations which may suddenly come to him as a surprise

Dr. A J Ochsner, Chicago—No surgeon has a very large personal experience in the excision of the cecum ascending colon and ileum, and for this reason the subject has never been thoroughly discussed before this Section It is one which should be discussed, because the success of the operation depends on the recognition of several simple principles It depends on this We must plan the operation so that the steps may be carried out with facility in order to reduce the amount of unnecessary manipulation The danger in every operation that has not been frequently performed is that we manipulate too much We find that in every form of surgery when the early mortality is exceedingly large it is not because the operation is especially difficult or dangerous but because we do not know how to go about it We kill the patients by unnecessary manipulation As to the manner in which this operation should be performed, I would say that a clamp should be placed on the ileum and the transverse colon at points beyond the diseased portion, and it should be remembered that we are in danger of wounding the buried portion of the duodenum If the two points of section of the ileum and colon are successfully grasped and the tissues behind the portion of the intestine to be removed are carefully secured with hemostatic forceps to prevent hemorrhage it is necessary only to avoid the ureter on the one side and the duodenum on the other As to the difference in the size of the two ends of the intestines to be united, the question of adjusting the size of large and small intestines should have been dropped many years ago Surgeons of experience will not meddle with this because it is absolutely unnecessary The two ends of the intestines are simply closed and a lateral anastomosis is made with sutures or an end to side anastomosis is made by inserting a Murphy button The same principles that we employ in intestinal surgery always come into play here We must have good nutrition in the intestine, there must be no tension or angulation and we must always see that serous surface is opposite serous surface By making use of these simple principles the operation may be performed within thirty minutes, and it is accompanied with as little danger as most of the operations on the intestine

Dr F Gregory Connell Leadville Colo —Perhaps the most important element in enterorrhaphy is the security the elimination of the danger of the yielding of the stitch The peritoneum and the muscularis do not guarantee this security while the submucosa does Hence the necessity of including the submucosa in the bite of the stitch Until comparatively recently it has been taught that it was possible to penetrate and not perforate this layer of the intestinal wall A short time ago this presentation of Dr Horsley's would not have been seriously considered and would have been looked on as dangerous We now know it is practically impossible to secure a proper hold in the submucosa without passing the suture through that layer The point as to the capillarity and infection would seem to be more or less theoretical, but it certainly would seem reasonable to suppose that this danger would be decreased by placing the knot within the lumen

Dr Horsley—I feel that some explanation should be made for taking about two hours to complete the operation There were adhesions to the abdominal wall the mesentery was short and thick and the vessels were large and tortuous The intestinal clamps slipped which caused delay by additional cleansing of the field After removal of the cecum and colon some involved mesenteric glands were found which necessitated resection of a portion of the ileum The time consumed in uniting the ileum and colon was sixteen minutes The specimen presented shows satisfactory union Dr Ochsner has called attention to the important surgical axiom that during an operation tissues should be manipulated as little as possible. Yet he recommends that big and small gut be joined by an end to side or a lateral method—thus leaving two or more distinct wounds to make and to close, whereas in the method described practically the whole process is an end to end union accomplished by a single row of continuous sutures This must be quicker and involve less manipulation than making an end to side or a lateral anastomosis and then closing the intestinal ends I have done the operation on the dog in eight minutes, with recovery

GALLSTONES IN THE COMMON DUCT *

ARCHIBALD MACLAREN, M.D
ST PAUL, MINN

Whether the formation of gallstones is due to chemical or to bacterial causes, it seems fairly certain that the stones are first formed in the gall bladder and are usually associated with recurring attacks of cholecystitis, usually of a subacute character Whether the inflammation of a gall bladder stands in the relation of cause or effect, it is apparently a clinical fact that, while we may occasionally see a primary cholecystitis without stones, we do not find a secondary attack occurring after any appreciable length of time without finding stones present either in the gall bladder or in the ducts I suppose it is possible for a patient to pass all of his stones through the common duct, and so cure himself, but my experience leads me to believe that such a result is almost impossible In fact, the passage into the intestine of a single stone is rare, and in the only case in which I have ever been able to prove such a passage and recover the small stone, there were many similar stones in the gall bladder, and the woman also had a chronic pancreatitis, evidently due to the temporary lodgement of the stone in the ampulla and consequent damming back of the infected bile into the pancreatic duct

After the formation of stones in the gall bladder they may, under favorable conditions, remain for long periods of time without causing any characteristic symptoms, the so-called slumbering gallstones

When, however, the gall bladder becomes infected or reinfected, gallstones being present, the stones apparently keep up the inflammation and irritate the gall bladder into recurrent and usually ineffectual colicky attempts to rid itself of its undesirable tenants

If the gall bladder succeeds in forcing a stone into the common duct it is very likely to lodge there, because the middle portion of this duct is more easily dilated than its distal extremity Mayo Robson finds that of all his gallstone cases one in five contains a stone in the common duct, while the Mayos have found one in seven at the time of the operation My own experience leads me to believe that Robson's figure is none too high

When a gallstone becomes lodged in the common duct there is an interference with biliary drainage, and infected bile from the gall bladder passes back into the hepatic ducts, setting up a more or less acute cholangitis After the lodging of a gall bladder stone in the common duct a later crop or a younger set of stones may be formed in the common or hepatic ducts behind it But the stone nearest to the intestine will be found to correspond in appearance and evident age to the gall bladder stones and not to the secondary hepatic duct concretions (Mayo)

---

* Read at the Fifty fifth Annual Session of the American Medical Association in the Section on Surgery and Anatomy and approved for publication by the Executive Committee Drs DeForest Willard Charles A Powers and J F Moore

It is of the utmost importance to entirely clear the ducts of all stones, for it is very distressing to our patients, and also to ourselves, to find that a secondary operation is necessary on account of a persistent biliary fistula, and this is the least of the evils that may follow

In one of my early cases I removed fifteen gallstones from an inflamed gall bladder, but the patient failed to improve, she grew steadily worse, and died on the fifth day At the postmortem examination I found several stones impacted low down in the common duct, no other cause of death being apparent

The presence of a stone in the common duct keeps up or aggravates the subacute cholecystitis which accompanies so many of these cases Contraction of the gall bladder wall soon takes place, which, if carried to its fullest extent, leaves the gall bladder a dense, hardened mass of cicatricial tissue, resembling a small tumor on the common duct Very recently I removed such an obliterated gall bladder that was not one-half inch in diameter

There are many analogies between the appendix and the gall bladder This chronic obliterative inflammation which affects them both is one of the closest and is another reason for cholecystectomy as against simple drainage of the gall bladder in cases when we believe that this process is well under way

Dr Maurice Richardson is unquestionably right when he says that cholecystectomy should be an operation of necessity, and not of choice, he is undoubtedly correct in his general propositions as to the advantages and greater safety of cholecystotomy over removal of the gall bladder, but occasionally, even in the moderately advanced cases of this class, removal of the common duct stone which is the cause of the obliterative inflammation, and draining of the infected gall bladder will not effect a cure

When should gallstones be removed from the gall bladder? There is still a considerable amount of uncertainty in the minds of many good men on this subject Kerr voices the sentiment of the greatest so-called conservatism, and sends many of his patients back to the internist and to the springs It would seem that perhaps his general mortality of 16 per cent, and his unexplainable mortality of 96 per cent in 75 "complicated cases" out of some 800 operations would be a strong argument against this plan of procedure My own answer to the above question would be that the operation should be done before the stones have reached the common duct or before other complications have had a chance to occur

If it were possible in any given case to predict the progress of a gall bladder stone, however innocent it might seem, then we should be justified in postponing removal but such a prediction is impossible Some cases give ample warning, in others, the lodging of the stone in the common duct is the first symptom of the disease or of its renewed activity

It would seem as though the only safe advice which can be given is that gallstones, wherever they are should be removed as soon as the diagnosis can be made with certainty As Mr E Stamnon Bishop in the London *Lancet* has recently said, no temporizing would be justifiable in the presence of a urinary calculus even though it were not producing active symptoms
